r-pampe	1.1.2	Implements the Panel Data Approach Method for program evaluation as developed in Hsiao, Ching and Ki Wan (2012). pampe estimates the effect of an intervention by comparing the evolution of the outcome for a unit affected by an intervention or treatment to the evolution of the unit had it not been affected by the intervention. / GPL-2	noarch
r-pamr	1.56	Some functions for sample classification in microarrays. / GPL-2	linux-64, osx-64, win-64
r-pan	1.6	It provides functions and examples for maximum likelihood estimation for generalized linear mixed models and Gibbs sampler for multivariate linear mixed models with incomplete data, as described in Schafer JL (1997) Imputation of missing covariates under a multivariate linear mixed model. Technical report 97-04, Dept. of Statistics, The Pennsylvania State University. / GPL-3	linux-64, osx-64, win-64
r-pander	0.6.3	Contains some functions catching all messages, 'stdout' and other useful information while evaluating R code and other helpers to return user specified text elements (like: header, paragraph, table, image, lists etc.) in 'pandoc' markdown or several type of R objects similarly automatically transformed to markdown format. Also capable of exporting/converting (the resulting) complex 'pandoc' documents to e.g. HTML, 'PDF', 'docx' or 'odt'. This latter reporting feature is supported in brew syntax or with a custom reference class with a smarty caching 'backend'. / AGPL-3	linux-64, osx-64, win-64
r-pandocfilters	0.1_3	The document converter 'pandoc' < http://pandoc.org/ > is widely used in the R community. One feature of 'pandoc' is that it can produce and consume JSON-formatted abstract syntax trees (AST). This allows to transform a given source document into JSON-formatted AST, alter it by so called filters and pass the altered JSON-formatted AST back to 'pandoc'. This package provides functions which allow to write such filters in native R code. Although this package is inspired by the Python package 'pandocfilters' < https://github.com/jgm/pandocfilters/ >, it provides additional convenience functions which make it simple to use the 'pandocfilters' package as a report generator. Since 'pandocfilters' inherits most of it's functionality from 'pandoc' it can create documents in many formats (for more information see < http://pandoc.org/ >) but is also bound to the same limitations as 'pandoc'. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-panelaggregation	0.1.1	Aggregate Business Tendency Survey Data (and other qualitative surveys) to time series at various aggregation levels. Run aggregation of survey data in a speedy, re-traceable and a easily deployable way. Aggregation is substantially accelerated by use of data.table. This package intends to provide an interface that is less general and abstract than data.table but rather geared towards survey researchers. / GPL-2	noarch
r-paneldata	1.0	Linear models for panel data: the fixed effect model and the random effect model / Artistic-2.0	noarch
r-panjen	1.6	A central decision in a parametric regression is how to specify the relation between an dependent variable and each explanatory variable. This package provides a semi-parametric tool for comparing different transformations of an explanatory variables in a parametric regression. The functions is relevant in a situation, where you would use a box-cox or Box-Tidwell transformations. In contrast to the classic power-transformations, the methods in this package allows for theoretical driven user input and the possibility to compare with a non-parametric transformation. / GPL-2	noarch
r-paperplanes	0.0.1	This is a data only package, that provides distances from a paper plane experiment. / GPL-3	noarch
r-parade	0.1	Tool for producing Pen's parade graphs, useful for visualizing inequalities in income, wages or other variables, as proposed by Pen (1971, ISBN: 978-0140212594). Income or another economic variable is captured by the vertical axis, while the population is arranged in ascending order of income along the horizontal axis. Pen's income parades provide an easy-to-interpret visualization of economic inequalities. / GPL-2	noarch
r-parallelize.dynamic	0.9_1	Passing a given function name or a call to the parallelize/parallelize_call functions analyses and executes the code, if possible in parallel. Parallel code execution can be performed locally or on remote batch queuing systems. / LGPL-3	noarch
r-parallelmap	1.4	Unified parallelization framework for multiple back-end, designed for internal package and interactive usage. The main operation is parallel mapping over lists. Supports 'local', 'multicore', 'mpi' and 'BatchJobs' mode. Allows tagging of the parallel operation with a level name that can be later selected by the user to switch on parallel execution for exactly this operation. / BSD_2_clause	noarch
r-parallelmcmccombine	1.0	Recent Bayesian Markov chain Monto Carlo (MCMC) methods have been developed for big data sets that are too large to be analyzed using traditional statistical methods. These methods partition the data into non-overlapping subsets, and perform parallel independent Bayesian MCMC analyses on the data subsets, creating independent subposterior samples for each data subset. These independent subposterior samples are combined through four functions in this package, including averaging across subset samples, weighted averaging across subsets samples, and kernel smoothing across subset samples. The four functions assume the user has previously run the Bayesian analysis and has produced the independent subposterior samples outside of the package; the functions use as input the array of subposterior samples. The methods have been demonstrated to be useful for Bayesian MCMC models including Bayesian logistic regression, Bayesian Gaussian mixture models and Bayesian hierarchical Poisson-Gamma models. The methods are appropriate for Bayesian hierarchical models with hyperparameters, as long as data values in a single level of the hierarchy are not split into subsets. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-parallelml	1.2	By sampling your data, running the provided classifier on these samples in parallel on your own machine and letting your models vote on a prediction, we return much faster predictions than the regular machine learning algorithm and possibly even more accurate predictions. / GPL-2	noarch
r-parallelpc	1.2	Parallelise constraint based causality discovery and causal inference methods. The parallelised algorithms in the package will generate the same results as that of the 'pcalg' package but will be much more efficient. / GPL-2	noarch
r-parallelsvm	0.1.9	By sampling your data, running the Support-Vector-Machine algorithm on these samples in parallel on your own machine and letting your models vote on a prediction, we return much faster predictions than the regular Support-Vector-Machine and possibly even more accurate predictions. / GPL-2	noarch
r-params	0.6.1	An interface to simplify organizing parameters used in a package, using external configuration files. This attempts to provide a cleaner alternative to options(). / GPL-2	noarch
r-paramtest	0.1.0	Run simulations or other functions while easily varying parameters from one iteration to the next. Some common use cases would be grid search for machine learning algorithms, running sets of simulations (e.g., estimating statistical power for complex models), or bootstrapping under various conditions. See the 'paramtest' documentation for more information and examples. / GPL-3	noarch
r-paran	1.5.2	An implementation of Horn's technique for numerically and graphically evaluating the components or factors retained in a principle components analysis (PCA) or common factor analysis (FA). Horn's method contrasts eigenvalues produced through a PCA or FA on a number of random data sets of uncorrelated variables with the same number of variables and observations as the experimental or observational data set to produce eigenvalues for components or factors that are adjusted for the sample error-induced inflation. Components with adjusted eigenvalues greater than one are retained. paran may also be used to conduct parallel analysis following Gorfeld's (1995) suggestions to reduce the likelihood of over-retention. / GPL-2	noarch
r-parentoffspring	1.0	Conduct the Parent-Offspring Test Using Monomorphic SNP Markers. The similarity to the parents is computed for each offspring, and a plot of similarity for all offspring is produced. One can keep the offspring above some threshold for the similarity for further studies. / GPL-2	noarch
r-parglm	0.1.3	Provides a parallel estimation method for generalized linear models without compiling with a multithreaded LAPACK or BLAS. / GPL-2	linux-64, osx-64, win-64
r-parmigene	1.0.2	The package provides a parallel estimation of the mutual information based on entropy estimates from k-nearest neighbors distances and algorithms for the reconstruction of gene regulatory networks. / AGPL-3	linux-64, osx-64, win-64
r-parse	0.1.0	Model-based clustering and identifying informative features based on regularization methods. The package includes three regularization methods - PAir-wise Reciprocal fuSE (PARSE) penalty proposed by Wang, Zhou and Hoeting (2016), the adaptive L1 penalty (APL1) and the adaptive pairwise fusion penalty (APFP). Heatmaps are included to shown the identification of informative features. / CC0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-parsetools	0.1.1	Tools and utilities for dealing with parse data. Parse data represents the parse tree as data with location and type information. This package provides functions for navigating the parse tree as a data frame. / GPL-2	noarch
r-partdsa	0.9.14	A novel tool for generating a piecewise constant estimation list of increasingly complex predictors based on an intensive and comprehensive search over the entire covariate space. / GPL-2	noarch
r-partiallyoverlapping	2.0	Tests for a comparison of two partially overlapping samples. A comparison of means using the partially overlapping samples t-test: See Derrick, Russ, Toher and White (2017), Test statistics for the comparison of means for two samples which include both paired observations and independent observations, Journal of Modern Applied Statistical Methods, 16(1). A comparison of proportions using the partially overlapping samples z-test: See Derrick, Dobson-Mckittrick, Toher and White (2015), Test statistics for comparing two proportions with partially overlapping samples. Journal of Applied Quantitative Methods, 10(3). / GPL-3	noarch
r-partialor	0.9	Computes Odds Ratio adjusted for a vector of possibly continuous covariates / GPL-2	noarch
r-partitionbefsp	1.0	A collection of functions that can be used to estimate selection and complementarity effects, sensu Loreau & Hector (2001) <doi:10.1038/35083573>, even in cases where data are only available for a random subset of species (i.e. incomplete sample-level data). A full derivation and explanation of the statistical corrections used here is available in Clark et al. (2019) <doi:10.1111/2041-210X.13285>. / GPL-3	noarch
r-partitionmap	0.5	Low-dimensional embedding, using Random Forests for multiclass classification / GPL-3	noarch
r-partitionmetric	1.1	partitionMetric computes a distance between two partitions of a set. / BSD_2_clause	noarch
r-partsm	1.1_2	This package performs basic functions to fit and predict periodic autoregressive time series models. These models are discussed in the book P.H. Franses (1996) Periodicity and Stochastic Trends in Economic Time Series, Oxford University Press. Data set analyzed in that book is also provided. NOTE: the package was orphaned during several years. It is now only maintained, but no major enhancement are expected, and the maintainer cannot provide any support. / GPL-2	noarch
r-party	1.3_3	A computational toolbox for recursive partitioning. The core of the package is ctree(), an implementation of conditional inference trees which embed tree-structured regression models into a well defined theory of conditional inference procedures. This non-parametric class of regression trees is applicable to all kinds of regression problems, including nominal, ordinal, numeric, censored as well as multivariate response variables and arbitrary measurement scales of the covariates. Based on conditional inference trees, cforest() provides an implementation of Breiman's random forests. The function mob() implements an algorithm for recursive partitioning based on parametric models (e.g. linear models, GLMs or survival regression) employing parameter instability tests for split selection. Extensible functionality for visualizing tree-structured regression models is available. The methods are described in Hothorn et al. (2006) <doi:10.1198/106186006X133933>, Zeileis et al. (2008) <doi:10.1198/106186008X319331> and Strobl et al. (2007) <doi:10.1186/1471-2105-8-25>. / GPL-2	linux-64, osx-64, win-64
r-pas	1.2.5	An R package for polygenic trait analysis. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pass.lme	0.9.0	Power and sample size calculation for testing fixed effect coefficients in multilevel linear mixed effect models with one or more than one independent populations. Laird, Nan M. and Ware, James H. (1982) <doi:10.2307/2529876>. / GPL-3	noarch
r-passport	0.2.0	Smooths the process of working with country names and codes via powerful parsing, standardization, and conversion utilities arranged in a simple, consistent API. Country name formats include multiple sources including the Unicode Common Locale Data Repository (CLDR, < http://cldr.unicode.org/ >) common-sense standardized names in hundreds of languages. / GPL-3	noarch
r-password	1.0_0	Create random passwords of letters, numbers and punctuation. / GPL-3	noarch
r-pastecs	1.3.21	Regularisation, decomposition and analysis of space-time series. The pastecs R package is a PNEC-Art4 and IFREMER (Benoit Beliaeff < Benoit.Beliaeff@ifremer.fr >) initiative to bring PASSTEC 2000 functionalities to R. / GPL-2	noarch
r-pastis	0.1_2	A pre-processor for mrBayes that assimilates sequences, taxonomic information and tree constraints as per xxx. The main functions of interest for most users will be <code>pastis_simple</code> , <code>pastis_main</code> and <code>conch</code> . The main analysis is conducted with <code>pastis_simple</code> or <code>pastis_main</code> followed by a manual execution of mrBayes (>3.2). The placement of taxa not contained in the tree constraint can be investigated using <code>conch</code> . / GPL-3	noarch
r-paswr	1.1	Data and functions for the book PROBABILITY and STATISTICS WITH R. / GPL-2	noarch
r-patchdvi	1.9.16	Functions to patch specials in .dvi files, or entries in .synctex files. Works with concordance=TRUE in Sweave or knitr to link sources to previews. / GPL-2	linux-64, osx-64, win-64
r-patchplot	0.1.5	Functions to generate scatterplots with images patches instead of usual glyphs, with associated utilities. / LGPL-3	noarch
r-patchsynctex	0.1_4	This utility eases the debugging of literate documents ('noweb' files) by patching the synchronization information (the '.synctex.gz' file) produced by 'pdflatex' with concordance information produced by 'Sweave' or 'knitr' and 'Sweave' or 'knitr' ; this allows for bilateral communication between a text editor (visualizing the 'noweb' source) and a viewer (visualizing the resultant 'PDF'), thus bypassing the intermediate 'TeX' file. / GPL-2	noarch
r-patentsview	0.2.2	Provides functions to simplify the 'PatentsView' API (< http://www.patentsview.org/api/doc.html >) query language, send GET and POST requests to the API's seven endpoints, and parse the data that comes back. / MIT	noarch
r-pathlibr	0.1.0	An OO Interface for path manipulation, emulating python's pathlib. / MIT	noarch
r-pathmapping	1.0.2	Functions to compute and display the area-based deviation between spatial paths and to compute a mapping based on minimizing area and distance-based cost. For details, see: Mueller, S. T., Perelman, B. S., & Veinott, E. S. (2016) <DOI:10.3758/s13428-015-0562-7>. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-patternator	0.1.0	Provides a set of functions to efficiently recognize and clean the continuous dorsal pattern of a female brown anole lizard (<i>Anolis sagrei</i>) traced from ‘ImageJ’, an open platform for scientific image analysis (see < https://imagej.net > for more information), and extract common features such as the pattern sinuosity indices, coefficient of variation, and max-min width. / GPL-2	noarch
r-pawacc	1.2.2	This is a collection of functions to process, format and store accelerometer data. / GPL-2	noarch
r-pawls	1.0.0	Efficient algorithms for fitting weighted least squares regression with eqn{L_{1}}{L1} regularization on both the coefficients and weight vectors, which is able to perform simultaneous variable selection and outliers detection efficiently. / GPL-2	linux-64, osx-64, win-64
r-paws.common	0.2.0	Functions for making low-level API requests to Amazon Web Services < https://aws.amazon.com >. The functions handle building, signing, and sending requests, and receiving responses. They are designed to help build higher-level interfaces to individual services, such as Simple Storage Service (S3). / Apache License (>= 2.0)	noarch
r-pbapply	1.4_2	A lightweight package that adds progress bar to vectorized R functions (*apply’). The implementation can easily be added to functions where showing the progress is useful (e.g. bootstrap). The type and style of the progress bar (with percentages or remaining time) can be set through options. Supports several parallel processing backends. / GPL-2	noarch
r-pbdncdf4	0.1_4	This package adds collective parallel read and write capability to the R package ncdf4 version 1.8. Typical use is as a parallel NetCDF4 file reader in SPMD style programming. Each R process reads and writes its own data in a synchronized collective mode, resulting in faster parallel performance. Performance improvement is conditional on a parallel file system. / GPL-3	linux-64, osx-64, win-64
r-pbdprof	0.3_1	MPI profiling tools. / Mozilla Public License 2.0	osx-64, win-64
r-pbdrpc	0.2_1	A very light implementation yet secure for remote procedure calls with unified interface via ssh (OpenSSH) or plink/plink.exe (PuTTY). / Mozilla Public License 2.0	linux-64, osx-64, win-64
r-pbdzmq	0.3_3	‘ZeroMQ’ is a well-known library for high-performance asynchronous messaging in scalable, distributed applications. This package provides high level R wrapper functions to easily utilize ‘ZeroMQ’. We mainly focus on interactive client/server programming frameworks. For convenience, a minimal ‘ZeroMQ’ library (4.2.2) is shipped with ‘pbdZMQ’, which can be used if no system installation of ‘ZeroMQ’ is available. A few wrapper functions compatible with ‘rzmq’ are also provided. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pbibd	1.3	The PBIB designs are important type of incomplete block designs having wide area of their applications for example in agricultural experiments, in plant breeding, in sample surveys etc. This package constructs various series of PBIB designs and assists in checking all the necessary conditions of PBIB designs and the association scheme on which these designs are based on. It also assists in calculating the efficiencies of PBIB designs with any number of associate classes. The package also constructs Youden-m square designs which are Row-Column designs for the two-way elimination of heterogeneity. The incomplete columns of these Youden-m square designs constitute PBIB designs. With the present functionality, the package will be of immense importance for the researchers as it will help them to construct PBIB designs, to check if their PBIB designs and association scheme satisfy various necessary conditions for the existence, to calculate the efficiencies of PBIB designs based on any association scheme and to construct Youden-m square designs for the two-way elimination of heterogeneity. R. C. Bose and K. R. Nair (1939) < http://www.jstor.org/stable/40383923 >. / GPL-2	noarch
r-pbimisc	1.0	A set of datasets and functions used in the book ‘Modele liniowe i mieszone w R, wraz z przykladami w analizie danych’. Datasets either come from real studies or are created to be as similar as possible to real studies. / GPL-2	noarch
r-pbivnorm	0.6.0	Provides a vectorized R function for calculating probabilities from a standard bivariate normal CDF. / GPL (>= 2)	linux-64, osx-64, win-32, win-64
r-pbkrtest	0.4.7	Test in mixed effects models. Attention is on mixed effects models as implemented in the ‘lme4’ package. This package implements a parametric bootstrap test and a Kenward Roger modification of F-tests for linear mixed effects models and a parametric bootstrap test for generalized linear mixed models. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-pbm	1.1.0	Binding models which are useful when analysing protein-ligand interactions by techniques such as Biolayer Interferometry (BLI) or Surface Plasmon Resonance (SPR). Naman B. Shah, Thomas M. Duncan (2014) < doi:10.3791/51383 >. Hoang H. Nguyen et al. (2015) < doi:10.3390/s150510481 >. After initial binding parameters are known, binding curves can be simulated and parameters can be varied. The models within this package may also be used to fit a curve to measured binding data using non-linear regression. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pbmcapply	1.5.0	A light-weight package helps you track and visualize the progress of parallel version of vectorized R functions (mc*apply). Parallelization (mc.core > 1) works only on *nix (Linux, Unix such as macOS) system due to the lack of fork() functionality, which is essential for mc*apply, on Windows. / MIT	linux-64, osx-64, win-64
r-pbo	1.3.4	Following the method of Bailey et al., computes for a collection of candidate models the probability of backtest overfitting, the performance degradation and probability of loss, and the stochastic dominance. / MIT	noarch
r-pbrackets	1.0	Adds different kinds of brackets to a plot, including braces, chevrons, parentheses or square brackets. / GPL (>= 2.0)	noarch
r-pbrf	1.0.0	Provides three ways to estimate the probability of being in response function (PBRF) The estimates are presented in Tsai, Luo and Crowley (2017) <doi: 10.1007/978-981-10-0126-0_10>. / GPL-2	linux-64, osx-64, win-64
r-pbs	1.1	Periodic B Splines Basis / GPL-2	noarch
r-pbsddesolve	1.12.4	Routines for solving systems of delay differential equations by interfacing numerical routines written by Simon N. Wood , with contributions by Benjamin J. Cairns. These numerical routines first appeared in Simon Wood's 'solv95' program. This package includes a vignette and a complete user's guide. 'PB-Sddesolve' originally appeared on CRAN under the name 'ddesolve'. That version is no longer supported. The current name emphasizes a close association with other PBS packages, particularly 'PBSmodelling'. / GPL-2	linux-64, osx-64, win-64
r-pbsmapping	2.72.1	This software has evolved from fisheries research conducted at the Pacific Biological Station (PBS) in 'Nanaimo', British Columbia, Canada. It extends the R language to include two-dimensional plotting features similar to those commonly available in a Geographic Information System (GIS). Embedded C code speeds algorithms from computational geometry, such as finding polygons that contain specified point events or converting between longitude-latitude and Universal Transverse Mercator (UTM) coordinates. Additionally, we include 'C' code developed by Angus Johnson for the 'Clipper' library, data for a global shoreline, and other data sets in the public domain. Under the user's R library directory '.libPaths()', specifically in './PBSmapping/doc', a complete user's guide is offered and should be consulted to use package functions effectively. / GPL-2	linux-64, osx-64, win-64
r-pbsmodelling	2.68.8	Provides software to facilitate the design, testing, and operation of computer models. It focuses particularly on tools that make it easy to construct and edit a customized graphical user interface ('GUI'). Although our simplified 'GUI' language depends heavily on the R interface to the 'Tcl/Tk' package, a user does not need to know 'Tcl/Tk'. Examples illustrate models built with other R packages, including 'PBSmapping', 'PBSddesolve', and 'BRugs'. A complete user's guide 'PBSmodelling-UG.pdf' shows how to use this package effectively. / GPL-2	linux-64, osx-64, win-64
r-pbv	0.2.1	Computes probabilities of the bivariate normal distribution in a vectorized R function (Drezner & Wesolowsky, 1990, <doi:10.1080/00949659008811236>). / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pca4ts	0.1	To seek for a contemporaneous linear transformation for a multivariate time series such that the transformed series is segmented into several lower-dimensional subseries, and those subseries are uncorrelated with each other both contemporaneously and serially. / GPL-2	linux-64, osx-64, win-64
r-pcamixdata	3.1	Implements principal component analysis, orthogonal rotation and multiple factor analysis for a mixture of quantitative and qualitative variables. / GPL (>= 2.0)	noarch
r-pcapp	1.9_7	Provides functions for robust PCA by projection pursuit. The methods are described in Croux et al. (2006) <doi:10.2139/ssrn.968376>, Croux et al. (2013) <doi:10.1080/00401706.2012.727746>, Todorov and Filzmoser (2013) <doi:10.1007/978-3-642-33042-1_31>. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
r-pcensmix	1.2_1	Functions for generating progressively Type-II censored data in a mixture structure and fitting models using a constrained EM algorithm. It can also create a progressive Type-II censored version of a given real dataset to be considered for model fitting. / GPL-2	noarch
r-pcfam	1.0	We provide several algorithms to compute the genotype ancestry scores (such as eigenvector projections) in the case where highly correlated individuals are involved. / GPL-2	noarch
r-pcg	1.1	The package solves linear system of equations $Ax=b$ by using Preconditioned Conjugate Gradient Algorithm where A is real symmetric positive definite matrix. A suitable preconditioner matrix may be provided by user. This can also be used to minimize quadratic function $(x'Ax)/2-bx$ for unknown x. / GPL-2	noarch
r-pch	1.3	Using piecewise constant hazards models is a very flexible approach for the analysis of survival data. The time line is divided into sub-intervals; for each interval, a different hazard is estimated using Poisson regression. / GPL-2	noarch
r-pcict	0.5_4	Provides a work-alike to R's POSIXct class which implements 360- and 365-day calendars in addition to the gregorian calendar. / GPL-2	linux-64, osx-64, win-64
r-peirt	0.2.4	Estimates the multidimensional polytomous Rasch model (Rasch, 1961) with conditional maximum likelihood estimation. / GPL-3	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pcit	1.5_3	Apply Partial Correlation coefficient with Information Theory (PCIT) to a correlation matrix. The PCIT algorithm identifies meaningful correlations to define edges in a weighted network. The algorithm can be applied to any correlation-based network including but not limited to gene co-expression networks. To reduce compute time by making use of multiple compute cores, simply run PCIT on a computer with has multiple cores and also has the Rmpi package installed. PCIT will then auto-detect the multicore environment and run in parallel mode without the need to rewrite your scripts. This makes scripts, using PCIT, portable across single core (or no Rmpi package installed) computers which will run in serial mode and multicore (with Rmpi package installed) computers which will run in parallel mode. / GPL-3	linux-64, osx-64, win-64
r-pco	1.0.1	Computation of the Pedroni (1999) panel cointegration test statistics. Reported are the empirical and the standardized values. / GPL-2	noarch
r-pcse	1.9.1	A function to estimate panel-corrected standard errors. Data may contain balanced or unbalanced panels. / GPL-3	noarch
r-pcsirr	0.1.0	Parallel Constraint Satisfaction (PCS) models are an increasingly common class of models in Psychology, with applications to reading and word recognition (McClelland & Rumelhart, 1981), judgment and decision making (Glöckner & Betsch, 2008; Glöckner, Hilbig, & Jekel, 2014), and several other fields (e.g. Read, Vanman, & Miller, 1997). In each of these fields, they provide a quantitative model of psychological phenomena, with precise predictions regarding choice probabilities, decision times, and often the degree of confidence. This package provides the necessary functions to create and simulate basic Parallel Constraint Satisfaction networks within R. / GPL-3	noarch
r-pdc	1.0.3	Permutation Distribution Clustering is a clustering method for time series. Dissimilarity of time series is formalized as the divergence between their permutation distributions. The permutation distribution was proposed as measure of the complexity of a time series. / GPL-3	linux-64, osx-64, win-64
r-pder	1.0_1	Data sets for the Panel Data Econometrics with R <doi:10.1002/9781119504641> book. / GPL-2	noarch
r-pdfestimator	0.1_3	Farmer, J., D. Jacobs (2108) <DOI:10.1371/journal.pone.0196937>. A non-parametric density estimator based on the maximum-entropy method. Accurately predicts a probability density function (PDF) for random data using a novel iterative scoring function to determine the best fit without overfitting to the sample. / GPL-2	linux-64, osx-64, win-64
r-pdftables	0.1	Allows the user to convert PDF tables to formats more amenable to analysis ('.csv', '.xml', or '.xlsx') by wrapping the PDFTables API. In order to use the package, the user needs to sign up for an API account on the PDFTables website (< https://pdftables.com/pdf-to-excel-api >). The package works by taking a PDF file as input, uploading it to PDFTables, and returning a file with the extracted data. / CC0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pdftools	2.2	Utilities based on ‘libpoppler’ for extracting text, fonts, attachments and meta-data from a PDF file. Also supports high quality rendering of PDF documents into PNG, JPEG, TIFF format, or into raw bitmap vectors for further processing in R. / MIT file LICENSE	linux-64, osx-64, win-32, win-64
r-pdist	1.2	Computes the euclidean distance between rows of a matrix X and rows of another matrix Y. Previously, this could be done by binding the two matrices together and calling ‘dist’, but this creates unnecessary computation by computing the distances between a row of X and another row of X, and likewise for Y. pdist strictly computes distances across the two matrices, not within the same matrix, making computations significantly faster for certain use cases. / GPL-3	linux-64, osx-64, win-64
r-pdm	0.1	Measures real distances in pictures. With PDM() function, you can choose one ‘*.jpg’ file, select the measure in mm of scale, starting and finishing point in the graphical scale, the name of the measure, and starting and finishing point of the measures. After, ask the user for a new measure. / GPL-3	noarch
r-pdsce	1.2	A package to compute and tune some positive definite and sparse covariance estimators / GPL-2	linux-64, osx-64, win-64
r-pdshiny	0.1.0	Interactive shiny application for working with Probability Distributions. Calculations and Graphs are provided. / GPL-2	noarch
r-peacock.test	1.0	The original definition of the two and three dimensional Kolmogorov-Smirnov two-sample test statistics given by Peacock (1983) is implemented. Two R-functions: peacock2 and peacock3, are provided to compute the test statistics in two and three dimensional spaces, respectively. Note the Peacock test is different from the Fasano and Franceschini test (1987). The latter is a variant of the Peacock test. / GPL-2	noarch
r-peacots	1.3	Calculates the periodogram of a time series, maximum-likelihood fits an Ornstein-Uhlenbeck state space (OUSS) null model and evaluates the statistical significance of periodogram peaks against the OUSS null hypothesis. The OUSS is a parsimonious model for stochastically fluctuating variables with linear stabilizing forces, subject to uncorrelated measurement errors. Contrary to the classical white noise null model for detecting cyclicity, the OUSS model can account for temporal correlations typically occurring in ecological and geological time series. / GPL-3	noarch
r-peakerror	2017.06.19	Chromatin immunoprecipitation DNA sequencing results in genomic tracks that show enriched regions or peaks where proteins are bound. This package implements fast C code that computes the true and false positives with respect to a database of annotated regions. / GPL-3	linux-64, osx-64, win-64
r-peakpick	0.11	Biologically inspired methods for detecting peaks in one-dimensional data, such as time series or genomics data. The algorithms were originally designed by Weber, Ramachandran, and Henikoff, see documentation. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-peakram	1.0.2	When working with big data sets, RAM conservation is critically important. However, it is not always enough to just monitor the size of the objects created. So-called copy-on-modify behavior, characteristic of R, means that some expressions or functions may require an unexpectedly large amount of RAM overhead. For example, replacing a single value in a matrix duplicates that matrix in the back-end, making this task require twice as much RAM as that used by the matrix itself. This package makes it easy to monitor the total and peak RAM used so that developers can quickly identify and eliminate RAM hungry code. / GPL-2	noarch
r-peaksegdisk	2019.08.16	Disk-based implementation of Functional Pruning Optimal Partitioning with up-down constraints <arXiv:1810.00117> for single-sample peak calling (independently for each sample and genomic problem), can handle huge data sets (10^7 or more). / GPL-3	linux-64, osx-64, win-64
r-peaksegdp	2017.08.16	Quadratic time dynamic programming algorithm can be used to compute an approximate solution to the problem of finding the most likely changepoints with respect to the Poisson likelihood, subject to a constraint on the number of segments, and the changes which must alternate: up, down, up, down, etc. For more info read < http://proceedings.mlr.press/v37/hocking15.html > PeakSeg: constrained optimal segmentation and supervised penalty learning for peak detection in count data by TD Hocking et al, proceedings of ICML2015. / GPL-3	linux-64, osx-64, win-64
r-pear	1.2	Package for estimating periodic autoregressive models. Datasets: monthly ozone and Fraser riverflow. Plots: periodic versions of boxplot, auto/partial correlations, moving-average expansion. / GPL-2	noarch
r-pearson7	1.0_2	Supports maximum likelihood inference for the Pearson VII distribution with shape parameter 3/2 and free location and scale parameters. This distribution is relevant when estimating the velocity of processive motor proteins with random detachment. / GPL-2	noarch
r-pearsonds	1.1	Implementation of the Pearson distribution system, including full support for the (d,p,q,r)-family of functions for probability distributions and fitting via method of moments and maximum likelihood method. / GPL-2	linux-64, osx-64, win-64
r-pearsonica	1.2_4	The Pearson-ICA algorithm is a mutual information-based method for blind separation of statistically independent source signals. It has been shown that the minimization of mutual information leads to iterative use of score functions, i.e. derivatives of log densities. The Pearson system allows adaptive modeling of score functions. The flexibility of the Pearson system makes it possible to model a wide range of source distributions including asymmetric distributions. The algorithm is designed especially for problems with asymmetric sources but it works for symmetric sources as well. / GPL-2	noarch
r-pedigreemm	0.3_3	Fit pedigree-based mixed-effects models. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pedigreetools	0.1	Tools to sort, edit and prune pedigrees and to extract the inbreeding coefficients and the relationship matrix (includes code for pedigrees from self-pollinated species). The use of pedigree data is central to genetics research within the animal and plant breeding communities to predict breeding values. The relationship matrix between the individuals can be derived from pedigree structure following the algorithms described for example in Vazquez et al., 2010 <doi:10.2527/jas.2009-1952>. / GPL-3	linux-64, osx-64, win-64
r-pedometrics	0.6.6	Functions to employ many of the tools and techniques used in the field of pedometrics. / GPL-2	linux-64, osx-64, win-64
r-peerperformance	2.2.1	Provides functions to perform the peer performance analysis of funds' returns as described in Ardia and Boudt (2018) <doi:10.1016/j.jbankfin.2017.10.014>. / GPL-2	noarch
r-pegrouptest	1.0	The population proportion using group testing can be estimated by different methods. Four functions including p.mle(), p.gart(), p.burrow() and p.order() are provided to implement four estimating methods including the maximum likelihood estimate, Gart's estimate, Burrow's estimate, and order statistic estimate. / GPL-2	noarch
r-pemm	1.0	This package provides functions to perform multivariate Gaussian parameter estimation based on data with abundance-dependent missingness. It implements a penalized Expectation-Maximization (EM) algorithm. The package is tailored for but not limited to proteomics data applications, in which a large proportion of the data are often missing-not-at-random with lower values (or absolute values) more likely to be missing. / GPL-3	noarch
r-penalized	0.9.5	Fitting possibly high dimensional penalized regression models. The penalty structure can be any combination of an L1 penalty (lasso and fused lasso), an L2 penalty (ridge) and a positivity constraint on the regression coefficients. The supported regression models are linear, logistic and Poisson regression and the Cox Proportional Hazards model. Cross-validation routines allow optimization of the tuning parameters. / GPL-2	linux-64, osx-64, win-64
r-pencoxfrail	1.0.1	A regularization approach for Cox Frailty Models by penalization methods is provided. / GPL-2	linux-64, osx-64, win-64
r-penmsm	0.99	Structured fusion Lasso penalized estimation of multi-state models with the penalty applied to absolute effects and absolute effect differences (i.e., effects on transition-type specific hazard rates). / GPL-2	linux-64, osx-64, win-64
r-pense	1.2.5	Robust penalized elastic net S and MM estimator for linear regression. The method is described in detail in Cohen Freue, G. V., Kepplinger, D., Salibian-Barrera, M., and Smucler, E. (2017) < https://gcohenfr.github.io/pdfs/PENSE_manuscript.pdf >. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pepsavims	0.9.1	An implementation of the data processing and data analysis portion of a pipeline named the PepSAVI-MS which is currently under development by the Hicks laboratory at the University of North Carolina. The statistical analysis package presented herein provides a collection of software tools used to facilitate the prioritization of putative bioactive peptides from a complex biological matrix. Tools are provided to deconvolute mass spectrometry features into a single representation for each peptide charge state, filter compounds to include only those possibly contributing to the observed bioactivity, and prioritize these remaining compounds for those most likely contributing to each bioactivity data set. / CC BY-NC-SA 4.0	noarch
r-peptides	2.4.1	Includes functions to calculate several physicochemical properties and indices for amino-acid sequences as well as to read and plot 'XVG' output files from the 'GROMACS' molecular dynamics package. / GPL-2	linux-64, osx-64, win-64
r-perc	0.1.3	To find the certainty of dominance interactions with indirect interactions being considered. / GPL-2	noarch
r-perccal	1.0	Contains functions which allow the user to compute confidence intervals quickly using the double bootstrap-based percentile calibrated ('perc-cal') method for linear regression coefficients. 'perccal_interval()' is the primary user-facing function within this package. / GPL-3	linux-64, osx-64, win-64
r-performanceanalytics	1.5.3	Collection of econometric functions for performance and risk analysis. In addition to standard risk and performance metrics, this package aims to aid practitioners and researchers in utilizing the latest research in analysis of non-normal return streams. In general, it is most tested on return (rather than price) data on a regular scale, but most functions will work with irregular return data as well, and increasing numbers of functions will work with P&L or price data where possible. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-periodictable	0.1.2	Provides a dataset containing properties for chemical elements. Helper functions are also provided to access some atomic properties. / GPL-3	noarch
r-perm	1.0_0	Perform Exact or Asymptotic permutation tests / GPL	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-permalgo	1.1	This version of the permutational algorithm generates a dataset in which event and censoring times are conditional on an user-specified list of covariates, some or all of which are time-dependent. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-permallows	1.13	Includes functions to work with the Mallows and Generalized Mallows Models. The considered distances are Kendall's-tau, Cayley, Hamming and Ulam and it includes functions for making inference, sampling and learning such distributions, some of which are novel in the literature. As a by-product, PerMallows also includes operations for permutations, paying special attention to those related with the Kendall's-tau, Cayley, Ulam and Hamming distances. It is also possible to generate random permutations at a given distance, or with a given number of inversions, or cycles, or fixed points or even with a given length on LIS (longest increasing subsequence). / GPL-2	linux-64, osx-64, win-64
r-permdep	1.0.2	Implementations of permutation approach to hypothesis testing for quasi-independence of truncation time and failure time. The implemented approaches are powerful against non-monotone alternatives and thereby offer protection against erroneous assumptions of quasi-independence. The proposed tests use either a conditional or an unconditional method to evaluate the permutation p-value. The conditional method was first developed in Tsai (1980) <doi:10.2307/2336059> and Efron and Petrosian (1992) <doi:10.1086/171931>. The unconditional method provides a valid approximation to the conditional method, yet computationally simpler and does not hold fixed the size of each risk sets. Users also have an option to carry out the proposed permutation tests in a parallel computing fashion. / GPL-3	linux-64, osx-64, win-64
r-permgs	0.2.5	Permutational group-sequential tests for time-to-event data based on the log-rank test statistic. Supports exact permutation test when the censoring distributions are equal in the treatment and the control group and approximate imputation-permutation methods when the censoring distributions are different. / GPL-3	noarch
r-permute	0.9.5	A set of restricted permutation designs for freely exchangeable, line transects (time series), and spatial grid designs plus permutation of blocks (groups of samples) is provided. 'permute' also allows split-plot designs, in which the whole-plots or split-plots or both can be freely-exchangeable or one of the restricted designs. The 'permute' package is modelled after the permutation schemes of 'Canoco 3.1' (and later) by Cajo ter Braak. / GPL-2	noarch
r-persiandictionary	1.0	Translate words from English to Persian (Over 67,000 words) / GPL-2	noarch
r-persianstemmer	1.0	Allows users to stem Persian texts for text analysis. / GPL-2	noarch
r-perturb	2.10	Use the perturb() function to evaluates collinearity by adding random noise to selected variables (Hendrickx & Pelzer 2004). The colldiag function() calculates condition numbers and variance decomposition proportions to test for collinearity and uncover its sources (Belsley 1980). / GPL-2	noarch
r-pesel	0.7.2	Automatic estimation of number of principal components in PCA with PEnalized SEmi-integrated Likelihood (PESEL). See Piotr Sobczyk, Malgorzata Bogdan, Julie Josse 'Bayesian dimensionality reduction with PCA using penalized semi-integrated likelihood' (2017) <doi:10.1080/10618600.2017.1340302>. / GPL-3	noarch
r-pet	0.5.1	Implementation of different analytic/direct and iterative reconstruction methods of radon transformed data such as PET data. It also offer the possibility to simulate PET data. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-petfinder	2.0.0	Wrapper of the ‘Petfinder API’ < https://www.petfinder.com/developers/v2/docs/ > that implements methods for interacting with and extracting data from the ‘Petfinder’ database. The ‘Petfinder REST API’ allows access to the ‘Petfinder’ database, one of the largest online databases of adoptable animals and animal welfare organizations across North America. / MIT	noarch
r-petitr	1.0	Calculates the relative growth rate (RGR) of a series of individuals by building a life table and solving the Lotka-Birch equation. (See Birch, L. C. 1948. The intrinsic rate of natural increase of an insect population. - Journal of Animal Ecology 17: 15-26) <doi:10.2307/1605>. / GPL-2	noarch
r-pgam	0.4.15	This work is an extension of the state space model for Poisson count data, Poisson-Gamma model, towards a semiparametric specification. Just like the generalized additive models (GAM), cubic splines are used for covariate smoothing. The semiparametric models are fitted by an iterative process that combines maximization of likelihood and backfitting algorithm. / GPL-2	linux-64, osx-64, win-64
r-pgbart	0.6.16	The Particle Gibbs sampler and Gibbs/Metropolis-Hastings sampler were implemented to fit Bayesian additive regression tree model. Construction of the model (training) and prediction for a new data set (testing) can be separated. Our reference papers are: Lakshminarayanan B, Roy D, Teh Y W. Particle Gibbs for Bayesian additive regression trees[C], Artificial Intelligence and Statistics. 2015: 553-561, < http://proceedings.mlr.press/v38/lakshminarayanan15.pdf > and Chipman, H., George, E., and McCulloch R. (2010) Bayesian Additive Regression Trees. The Annals of Applied Statistics, 4,1, 266-298, <doi:10.1214/09-aoas285>. / GPL-2	linux-64, osx-64, win-64
r-pgdraw	1.1	Generates random samples from the Polya-Gamma distribution using an implementation of the algorithm described in J. Windle’s PhD thesis (2013) < https://repositories.lib.utexas.edu/bitstream/handle/2152/21842/WINDLE-DISSERTATION-2013.pdf >. The underlying implementation is in C. / GPL-3	linux-64, osx-64, win-64
r-pgee	1.5	Fits penalized generalized estimating equations to longitudinal data with high-dimensional covariates. / GPL-2	noarch
r-pgee.mixed	0.1.0	Perform simultaneous estimation and variable selection for correlated bivariate mixed outcomes (one continuous outcome and one binary outcome per cluster) using penalized generalized estimating equations. In addition, clustered Gaussian and binary outcomes can also be modeled. The SCAD, MCP, and LASSO penalties are supported. Cross-validation can be performed to find the optimal regularization parameter(s). / GPL-2	linux-64, osx-64, win-64
r-pgls	0.0_1	Based on the Generalized Least Square model for comparative Phylogenetics (ref). / GPL-2	noarch
r-pgm2 < https://sites.google.com/site/robmccallfield/ > >‘_	1.0_1	Construction method of nested resolvable designs from a projective geometry defined on Galois field of order 2. The obtained Resolvable designs are used to build uniform design. The presented results are based on < https://eudml.org/doc/219563 > and A. Boudraa et al. (See references). / GPL-3	noarch
r-pgmm	1.2.3	Carries out model-based clustering or classification using parsimonious Gaussian mixture models. McNicholas and Murphy (2008) <doi:10.1007/s11222-008-9056-0>, McNicholas (2010) <doi:10.1016/j.jsps.2009.11.006>, McNicholas and Murphy (2010) <doi:10.1093/bioinformatics/btq498>, McNicholas et al. (2010) <doi:10.1016/j.csda.2009.02.011>. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pgnorm	2.0	Evaluation of the pdf and the cdf of the univariate, noncentral, p-generalized normal distribution. Sampling from the univariate, noncentral, p-generalized normal distribution using either the p-generalized polar method, the p-generalized rejecting polar method, the Monty Python method, the Ziggurat method or the method of Nardon and Pianca. The package also includes routines for the simulation of the bivariate, p-generalized uniform distribution and the simulation of the corresponding angular distribution. / GPL-2	noarch
r-pgsc	1.0.0	Computes the generalized synthetic control estimator described in Powell (2017) <doi:10.7249/WR1142>. Provides both point estimates, and hypothesis testing. / GPL-2	linux-64, osx-64, win-64
r-ph2bayes	0.0.2	An implementation of Bayesian single-arm phase II design methods for binary outcome based on posterior probability (Thall and Simon (1994) <doi:10.2307/2533377>) and predictive probability (Lee and Liu (2008) <doi:10.1177/1740774508089279>). / GPL-3	linux-64, osx-64, win-64
r-ph2hetero	1.0.2	Implementation of Jones (2007) <doi:10.1016/j.cct.2007.02.008> , Tournoux-Facon (2011) <doi:10.1002/sim.4148> and Parashar (2016) <doi:10.1002/pst.1742> designs. / GPL-3	linux-64, osx-64, win-64
r-ph2mult	0.1.1	Provide multinomial design methods under intersection-union test (IUT) and union-intersection test (UIT) scheme for Phase II trial. The design types include : Minimax (minimize the maximum sample size), Optimal (minimize the expected sample size), Admissible (minimize the Bayesian risk) and Max-power (maximize the exact power level). / GPL-2	noarch
r-phase123	2.1	Contains three simulation functions for implementing the entire Phase 123 trial and the separate Eff-Tox and Phase 3 portions of the trial, which may be beneficial for use on clusters. The functions AssignEffTox() and RandomizeEffTox() assign doses to patient cohorts during phase 12 and Reoptimize() determines the optimal dose to continue with during Phase 3. The functions ReturnMeansAgent() and ReturnMeanControl() gives the true mean survival for the agent doses and control and ReturnOCS() gives the operating characteristics of the design. / GPL-2	linux-64, osx-64, win-64
r-phd	0.1	Provides permutation methods for testing in high-dimensional linear models. The tests are often robust against heteroscedasticity and non-normality and usually perform well under anti-sparsity. See Hemerik and Goeman (2018) <doi:10.1007/s11749-017-0571-1>. / GPL-3	noarch
r-pheatmap	1.0.12	Implementation of heatmaps that offers more control over dimensions and appearance. / GPL-2	noarch
r-phenability	2.0	An alternative to carrying out phenotypic adaptability and stability analyses, taking into account nonparametric statistics. Can be used as a robust approach, less sensitive to departures from common genotypic, environmental, and GxE effects data assumptions (e.g., normal distribution of errors). / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-phenex	1.4.5	Provides some easy-to-use functions for spatial analyses of (plant-) phenological data sets and satellite observations of vegetation. / GPL-2	linux-64, osx-64, win-64
r-pheno	1.6	Provides some easy-to-use functions for time series analyses of (plant-) phenological data sets. These functions mainly deal with the estimation of combined phenological time series and are usually wrappers for functions that are already implemented in other R packages adapted to the special structure of phenological data and the needs of phenologists. Some date conversion functions to handle Julian dates are also provided. / GPL-2	linux-64, osx-64, win-64
r-phenocamapi	0.1.5	A bundle to facilitate working with PhenoCam timeseries and data. The user would be able to obtain phenological time-series and site metadata from the PhenoCam network < https://phenocam.sr.unh.edu/webcam/ >. / AGPL-3	noarch
r-pheval	0.5.4	Provides tools for the evaluation of the goodness of fit and the predictive capacity of the proportional hazards model. / GPL (>= 2.0)	noarch
r-phidelta	1.0.1	Analysis of features by phi delta diagrams. In particular, functions for reading data and calculating phi and delta as well as the functionality to plot it. Moreover it is possible to do further analysis on the data by generating rankings. For more information on phi delta diagrams, see also Giuliano Armano (2015) <doi:10.1016/j.ins.2015.07.028>. / GPL-2	noarch
r-phmm	0.7.1	Fits proportional hazards model incorporating random effects using an EM algorithm using Markov Chain Monte Carlo at E-step. Vaida and Xu (2000) <DOI:10.1002/1097-0258(20001230)19:24%3C3309::AID-SIM825%3E3.0.CO;2-9>. / GPL-3	linux-64, osx-64, win-64
r-phonenum	0.2.2	Convert English letters to numbers or numbers to English letters as on a telephone keypad. When converting letters to numbers, a character vector is returned with A, B, or C becoming 2, D, E, or F becoming 3, etc. When converting numbers to letters, a character vector is returned with multiple elements (i.e., 2 becomes a vector of A, B, and C). / MIT	noarch
r-phonics	1.3.2	Provides a collection of phonetic algorithms including Soundex, Metaphone, NYSIIS, Caverphone, and others. / BSD_2_clause	linux-64, osx-64, win-64
r-phontools	0.2.2	Contains tools for the organization, display, and analysis of the sorts of data frequently encountered in phonetics research and experimentation, including the easy creation of IPA vowel plots, and the creation and manipulation of WAVE audio files. / BSD_2_clause	noarch
r-phreeqc	3.4.10	A geochemical modeling program developed by the US Geological Survey that is designed to perform a wide variety of aqueous geochemical calculations, including speciation, batch-reaction, one-dimensional reactive-transport, and inverse geochemical calculations. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-phtt	3.1.2	The package provides estimation procedures for panel data with large dimensions n , T , and general forms of unobservable heterogeneous effects. Particularly, the estimation procedures are those of Bai (2009) and Kneip, Sickles, and Song (2012), which complement one another very well: both models assume the unobservable heterogeneous effects to have a factor structure. The method of Bai (2009) assumes that the factors are stationary, whereas the method of Kneip et al. (2012) allows the factors to be non-stationary. Additionally, the ‘phtt’ package provides a wide range of dimensionality criteria in order to estimate the number of the unobserved factors simultaneously with the remaining model parameters. / GPL-2	noarch
r-phuassess	1.1	Assessment of habitat selection by means of the permutation-based combination of sign tests (Fattorini et al., 2014 <DOI:10.1007/s10651-013-0250-7>). To exemplify the application of this procedure, habitat selection is assessed for a population of European Brown Hares settled in central Italy. / GPL-2	noarch
r-phuse	0.1.8	Make it easy to review, download and execute scripts stored in Github ‘phuse-scripts’ repository < https://github.com/phuse-org/phuse-scripts >. Some examples included show the web application framework using the script meta-data. The ‘PhUSE’ is Pharmaceutical Users Software Exchange < http://www.phuse.eu >. / MIT	noarch
r-phyclust	0.1_2	Phylogenetic clustering (phyloclustering) is an evolutionary Continuous Time Markov Chain model-based approach to identify population structure from molecular data without assuming linkage equilibrium. The package phyclust (Chen 2011) provides a convenient implementation of phyloclustering for DNA and SNP data, capable of clustering individuals into subpopulations and identifying molecular sequences representative of those subpopulations. It is designed in C for performance, interfaced with R for visualization, and incorporates other popular open source programs including ms (Hudson 2002) <doi:10.1093/bioinformatics/18.2.337>, seq-gen (Rambaut and Grassly 1997) <doi:10.1093/bioinformatics/13.3.235>, Hap-Clustering (Tzeng 2005) <doi:10.1002/gepi.20063> and PAML baseml (Yang 1997, 2007) <doi:10.1093/bioinformatics/13.5.555>, <doi:10.1093/molbev/msm088>, for simulating data, additional analyses, and searching the best tree. See the phyclust website for more information, documentations and examples. / GPL-2	linux-64, osx-64, win-64
r-phylin	2.0	The spatial interpolation of genetic distances between samples is based on a modified kriging method that accepts a genetic distance matrix and generates a map of probability of lineage presence. This package also offers tools to generate a map of potential contact zones between groups with user-defined thresholds in the tree to account for old and recent divergence. Additionally, it has functions for IDW interpolation using genetic data and midpoints. / GPL-2	noarch
r-phyloclim	0.9.5	Implements some methods in phyloclimatic modeling: estimation of ancestral climatic niches, age-range-correlation, niche equivalency test and background-similarity test. / GPL-2	noarch
r-phylogr	1.0.10	Manipulation and analysis of phylogenetically simulated data sets and phylogenetically based analyses using GLS. / GPL-2	noarch
r-phylogram	2.1.0	Contains functions for developing phylogenetic trees as deeply-nested lists (dendrogram objects). Enables bi-directional conversion between dendrogram and phylo objects (see Paradis et al (2004) <doi:10.1093/bioinformatics/btg412>), and features several tools for command-line tree manipulation and import/export via Newick parenthetical text. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-phyloland	1.3	Phyloland package models a space colonization process mapped onto a phylogeny, it aims at estimating limited dispersal and ecological competitive exclusion in a Bayesian MCMC statistical phylogeographic framework (please refer to phyloland-package help for details.) / GPL-2	linux-64, osx-64, win-64
r-phylomeasures	2.1	Given a phylogenetic tree T and an assemblage S of species represented as a subset of tips in T, we want to compute a measure of the diversity of the species in S with respect to T. The current package offers efficient algorithms that can process large phylogenetic data for several such measures. Most importantly, the package includes algorithms for computing efficiently the standardized versions of phylogenetic measures and their p-values, which are essential for null model comparisons. Among other functions, the package provides efficient computation of richness-standardized versions for indices such as the net relatedness index (NRI), nearest taxon index (NTI), phylogenetic diversity index (PDI), and the corresponding indices of two-sample measures. The package also introduces a new single-sample measure, the Core Ancestor Cost (CAC); the package provides functions for computing the value and the standardised index of the CAC and, more than that, there is an extra function available that can compute exactly any statistical moment of the measure. The package supports computations under different null models, including abundance-weighted models. / GPL-3	linux-64, osx-64, win-64
r-phylometrics	0.0.1	Provides functions to estimate statistical errors of phylogenetic metrics particularly to detect binary trait influence on diversification, as well as a function to simulate trees with fixed number of sampled taxa and trait prevalence. / GPL-2	noarch
r-phylotate	1.3	Functions to read and write APE-compatible phylogenetic trees in NEXUS and Newick formats, while preserving annotations. / MIT	noarch
r-phylotools	0.2.2	A collection of tools for building RAxML supermatrix using PHYLIP or aligned FASTA files. These functions will be useful for building large phylogenies using multiple markers. / GPL-2	noarch
r-phyreg	1.0.2	Provides general linear model facilities (single y-variable, multiple x-variables with arbitrary mixture of continuous and categorical and arbitrary interactions) for cross-species data. The method is, however, based on the nowadays rather uncommon situation in which uncertainty about a phylogeny is well represented by adopting a single polytomous tree. The theory is in A. Grafen (1989, Proc. R. Soc. B 326, 119-157) and aims to cope with both recognised phylogeny (closely related species tend to be similar) and unrecognised phylogeny (a polytomy usually indicates ignorance about the true sequence of binary splits). / GPL-2 GPL-3	noarch
r-physactbedrest	1.0	Contains a function to categorize accelerometer readings collected in free-living (e.g., for 24 hours/day for 7 days), preprocessed and compressed as counts (unit-less value) in a specified time period termed epoch (e.g., 1 minute) as either bedrest (sleep) or active. The input is a matrix with a timestamp column and a column with number of counts per epoch. The output is the same dataframe with an additional column termed bedrest. In the bedrest column each line (epoch) contains a function-generated classification 'br' or 'a' denoting bedrest/sleep and activity, respectively. The package is designed to be used after wear/nonwear marking function in the 'PhysicalActivity' package. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-physicalactivity	0.2.2	It provides a function wearingMarking for classification of monitor wear and nonwear time intervals in accelerometer data collected to assess physical activity. The package also contains functions for making plot for accelerometer data and obtaining the summary of various information including daily monitor wear time and the mean monitor wear time during valid days. The revised package version 0.2-1 improved the functions in the previous version regarding speed and robustness. In addition, several functions were added: markDelivery can classify days for ActiGraph delivery by mail; markPAI can categorize physical activity intensity level based on user-defined cut-points of accelerometer counts. It also supports importing ActiGraph AGD files with readActigraph and queryActigraph functions. The package also better supports time zones and daylight saving. / GPL-3	noarch
r-physiology	1.2.1	A variety of formulae are provided for estimation of physiologic characteristics of infants, children, and adults. Calculations include: body surface area, ideal weight, airway dead-space, the alveolar gas equation, and GFR. Each formula is referenced to the original publication. Future functions will cover more material with a focus on anaesthesia, critical care and peri-operative medicine. / GPL-3	linux-64, osx-64, win-64
r-picasso	1.3.1	Computationally efficient tools for fitting generalized linear model with convex or non-convex penalty. Users can enjoy the superior statistical property of non-convex penalty such as SCAD and MCP which has significantly less estimation error and overfitting compared to convex penalty such as lasso and ridge. Computation is handled by multi-stage convex relaxation and the Pathwise CALibrated Sparse Shooting algorithm (PICASSO) which exploits warm start initialization, active set updating, and strong rule for coordinate preselection to boost computation, and attains a linear convergence to a unique sparse local optimum with optimal statistical properties. The computation is memory-optimized using the sparse matrix output. / GPL-3	linux-64, osx-64, win-64
r-pieceexpintensity	1.0.4	This function fits a reversible jump Bayesian piecewise exponential model that also includes the intensity of each event considered along with the rate of events. / GPL-2	linux-64, osx-64, win-64
r-piggyback	0.0.10	Because larger (> 50 MB) data files cannot easily be committed to git, a different approach is required to manage data associated with an analysis in a GitHub repository. This package provides a simple work-around by allowing larger (up to 2 GB) data files to piggyback on a repository as assets attached to individual GitHub releases. These files are not handled by git in any way, but instead are uploaded, downloaded, or edited directly by calls through the GitHub API. These data files can be versioned manually by creating different releases. This approach works equally well with public or private repositories. Data can be uploaded and downloaded programmatically from scripts. No authentication is required to download data from public repositories. / GPL-3	noarch
r-pigshift	1.0.1	Fits models of gene expression evolution to expression data from coregulated groups of genes, assuming inverse gamma distributed rate variation. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pijavski	1.0	Global univariate minimization of Lipschitz functions is performed by using Pijavski method, which was published in Pijavski (1972) <DOI:10.1016/0041-5553(72)90115-2>. / LGPL-3	linux-64, osx-64, win-64
r-pillar	1.3.1	Provides a ‘pillar’ generic designed for formatting columns of data using the full range of colours provided by modern terminals. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-pinfsc50	1.1.0	Genomic data for the plant pathogen Phytophthora infestans. It includes a variant file (‘VCF’), a sequence file (‘FASTA’) and an annotation file (‘GFF’). This package is intended to be used as example data for packages that work with genomic data. / GPL-3	noarch
r-pingr	1.1.2	Check if a remote computer is up. It can either just call the system ping command, or check a specified TCP port. / MIT	linux-64, osx-64, win-64
r-pinnacle.api	2.3.3	An interface to the API by Pinnacle that allows Pinnacle customers to interact with the sports market data in R. See < https://www.pinnacle.com/en/api > for more information. The Pinnacle API can be used to place wagers, retrieve line information, retrieve account information. Please be aware that the TOC of Pinnacle apply < https://www.pinnacle.com/en/termsandconditions >. An account with Pinnacle is necessary to use the Pinnacle API. / GPL-3	noarch
r-pinochet	0.1.0	Packages data about the victims of the Pinochet regime as compiled by the Chilean National Commission for Truth and Reconciliation Report (1991, ISBN:9780268016463). / MIT	noarch
r-pinp	0.0.8	A ‘PNAS’-alike style for ‘rmarkdown’, derived from the ‘Proceedings of the National Academy of Sciences of the United States of America’ (‘PNAS’, see < https://www.pnas.org >) ‘LaTeX’ style, and adapted for use with ‘markdown’ and ‘pandoc’. / GPL-3	noarch
r-pins	0.1.2	Pin remote resources into a local cache to work offline, improve speed and avoid recomputing; discover and share resources in local folders, ‘GitHub’, ‘Kaggle’ or ‘RStudio Connect’. Resources can be anything from ‘CSV’, ‘JSON’, or image files to arbitrary R objects. / Apache License 2.0	noarch
r-pipefitter	0.1.2	To take nested function calls and convert them to a more readable form using pipes from package ‘magrittr’. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pipegs	0.4	Code for various permutation p-values estimation methods for gene set test. The description of corresponding methods can be found in the dissertation of Yu He(2016) Efficient permutation P-value estimation for gene set tests < https://searchworks.stanford.edu/view/11849351 >. One of the methods also corresponds to the paper Permutation p-value approximation via generalized Stolarsky invariance <arXiv:1603.02757>. / GPL-2	noarch
r-pipeliner	0.1.1	A framework for defining ‘pipelines’ of functions for applying data transformations, model estimation and inverse-transformations, resulting in predicted value generation (or model-scoring) functions that automatically apply the entire pipeline of functions required to go from input to predicted output. / Apache License 2.0	noarch
r-piper	0.6.1	Provides various styles of function chaining methods: Pipe operator, Pipe object, and pipeline function, each representing a distinct pipeline model yet sharing almost a common set of features: A value can be piped to the first unnamed argument of a function and to dot symbol in an enclosed expression. The syntax is designed to make the pipeline more readable and friendly to a wide range of operations. / MIT	noarch
r-pips	1.0.1	Generate Predicted Interval Plots. Simulate and plot confidence intervals of an effect estimate given observed data and a hypothesis about the distribution of future data. / GPL-2	noarch
r-piton	0.1.1	A wrapper around the ‘Parsing Expression Grammar Template Library’, a C11 library for generating Parsing Expression Grammars, that makes it accessible within Repp. With this, developers can implement their own grammars and easily expose them in R packages. / MIT	linux-64, osx-64, win-64
r-pivotalr	0.1.18	Provides an R interface for the Pivotal Data stack running on ‘PostgreSQL’, ‘Greenplum’ or ‘Apache HAWQ (incubating)’ databases with parallel and distributed computation ability for big data processing. ‘PivotalR’ provides an R interface to various database operations on tables or views. These operations are almost the same as the corresponding native R operations. Thus users of R do not need to learn ‘SQL’ when they operate on objects in the database. It also provides a wrapper for ‘Apache MADlib (incubating)’, which is an open-source library for parallel and scalable in-database analytics. / GPL-2	linux-64, osx-64, win-64
r-pivotaltrackr	0.1.0	‘Pivotal Tracker’ < https://www.pivotaltracker.com > is a project management software-as-a-service that provides a REST API. This package provides an R interface to that API, allowing you to query it and work with its responses. / MIT	noarch
r-pixels	0.1.0	Provides tools to show and draw image pixels using ‘HTML’ widgets and ‘Shiny’ applications. It can be used to visualize the ‘MNIST’ dataset for hand-written digit recognition or to create new image recognition datasets. / MIT	noarch
r-pixmap	0.4.1	Functions for import, export, plotting and other manipulations of bitmapped images. / GPL-2	noarch
r-pk	1.3.4	Estimation of pharmacokinetic parameters using non-compartmental theory. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pkconverter	1.3	Pharmacokinetics is the study of drug absorption, distribution, metabolism, and excretion. The pharmacokinetics model explains that how the drug concentration change as the drug moves through the different compartments of the body. For pharmacokinetic modeling and analysis, it is essential to understand the basic pharmacokinetic parameters. All parameters are considered, but only some of parameters are used in the model. Therefore, we need to convert the estimated parameters to the other parameters after fitting the specific pharmacokinetic model. This package is developed to help this converting work. For more detailed explanation of pharmacokinetic parameters, see Gabrielsson and Weiner (2007), ISBN-10: 9197651001; Benet and Zia-Amirhosseini (1995) <DOI: 10.1177/019262339502300203>; Mould and Upton (2012) <doi:10.1038/psp.2012.4>; Mould and Upton (2013) <doi:10.1038/psp.2013.14>. / GPL-2	noarch
r-pkgbuild	1.0.3	Provides functions used to build R packages. Locates compilers needed to build R packages on various platforms and ensures the PATH is configured appropriately so R can use them. / GPL-3	linux-64, noarch, osx-64, win-32, win-64
r-pkgcond	0.1.0	This provides utilities for creating classed error and warning conditions based on where the error originated. / GPL-2	noarch
r-pkgconfig	2.0.2	Set configuration options on a per-package basis. Options set by a given package only apply to that package, other packages are unaffected. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-pkgdown	1.4.1	Generate an attractive and useful website from a source package. ‘pkgdown’ converts your documentation, vignettes, ‘README’, and more to ‘HTML’ making it easy to share information about your package online. / MIT	noarch
r-pkgkitten	0.1.4	Provides a function kitten() which creates cute little packages which pass R package checks. This sets it apart from package.skeleton() which it calls, and which leaves imperfect files behind. As this is not exactly helpful for beginners, kitten() offers an alternative. / GPL-2	noarch
r-pkgload	1.0.2	Simulates the process of installing a package and then attaching it. This is a key part of the ‘devtools’ package as it allows you to rapidly iterate while developing a package. / GPL-3	linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pkgmaker	0.27	Provides some low-level utilities to use for package development. It currently provides managers for multiple package specific options and registries, vignette, unit test and bibtex related utilities. It serves as a base package for packages like NMF, RcppOctave, doRNG, and as an incubator package for other general purposes utilities, that will eventually be packaged separately. It is still under heavy development and changes in the interface(s) are more than likely to happen. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-pki	0.1_5	PKI functions such as verifying certificates, RSA encryption and signing which can be used to build PKI infrastructure and perform cryptographic tasks. / GPL-2 GPL-3 file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-pkmon	1.0	We implement two least-squares estimators under k-monotony constraint using a method based on the Support Reduction Algorithm from Groeneboom et al (2008) <DOI:10.1111/j.1467-9469.2007.00588.x>. The first one is a projection estimator on the set of k-monotone discrete functions. The second one is a projection on the set of k-monotone discrete probabilities. This package provides functions to generate samples from the spline basis from Lefevre and Loisel (2013) <DOI:10.1239/jap/1378401239>, and from mixtures of splines. / CC BY 4.0	noarch
r-pkpdmodels	0.3.2	Provides functions to evaluate common pharmacokinetic/pharmacodynamic models and their gradients. / GPL-2	noarch
r-pksea	0.0.1	A tool for inferring kinase activity changes from phosphoproteomics data. 'pKSEA' uses kinase-substrate prediction scores to weight observed changes in phosphopeptide abundance to calculate a phosphopeptide-level contribution score, then sums up these contribution scores by kinase to obtain a phosphoproteome-level kinase activity change score (KAC score). 'pKSEA' then assesses the significance of changes in predicted substrate abundances for each kinase using permutation testing. This results in a permutation score (pKSEA significance score) reflecting the likelihood of a similarly high or low KAC from random chance, which can then be interpreted in an analogous manner to an empirically calculated p-value. 'pKSEA' contains default databases of kinase-substrate predictions from 'NetworkKIN' (NetworKINPred_db) < http://networkin.info > Horn, et. al (2014) <doi:10.1038/nmeth.2968> and of known kinase-substrate links from 'PhosphoSitePlus' (KSEAdb) < https://www.phosphosite.org/ > Hornbeck PV, et. al (2015) <doi:10.1093/nar/gku1267>. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pla	0.2	Parallel Line Assays: Completely randomized design, Randomized Block design, and Latin squares design. Balanced data are fitted as described in the Ph.Eur. In the presence of missing values complete data analysis can be performed (with computation of Fieller's confidence intervals for the estimated potency), or imputation of values can be applied. The package contains a script such that a pdf-document with a report of an analysis of an assay can be produced from an input file with data of the assay. Here no knowledge of R is needed by the user. / GPL-2	noarch
r-plac	0.1.1	A semi-parametric estimation method for the Cox model with left-truncated data using augmented information from the marginal of truncation times. / GPL-3	linux-64, osx-64, win-64
r-plan	0.4.3	Supports the creation of 'burndown' charts and 'ganttt' diagrams. / GPL-2	noarch
r-planesmuestra	0.1	Calculates an acceptance sampling plan, (sample size and acceptance number) based in MIL STD 105E, Dodge Romig and MIL STD 414 tables and procedures. The arguments for each function are related to lot size, inspection level and quality level. The specific plan operating curve (OC), is calculated by the binomial distribution. / GPL-2	noarch
r-planets	0.1.0	The goal of 'planets' is to provide of very simple and accessible data containing basic information from all known planets. / MIT	noarch
r-planor	1.5.1	Automatic generation of regular factorial designs, including fractional designs, orthogonal block designs, row-column designs and split-plots. / GPL-2	linux-64, osx-64, win-64
r-plantecophys	1.4.4	Coupled leaf gas exchange model, A-Ci curve simulation and fitting, Ball-Berry stomatal conductance models, leaf energy balance using Penman-Monteith, Cowan-Farquhar optimization, humidity unit conversions. See Dursma (2015) <doi:10.1371/journal.pone.0143346>. / GPL-3	noarch
r-plaqr	2.0	Estimation, prediction, thresholding, transformation, and plotting for partially linear additive quantile regression. Intuitive functions for fitting and plotting partially linear additive quantile regression models. Uses and works with functions from the 'quantreg' package. / GPL-2	noarch
r-playerratings	1.0.3	Implements schemes for estimating player or team skill based on dynamic updating. Implemented methods include Elo, Glicko, Glicko-2 and Stephenson. Contains pdf documentation of a reproducible analysis using approximately two million chess matches. / GPL-3	linux-64, osx-64, win-64
r-plde	0.1.2	We present a penalized log-density estimation method using Legendre polynomials with lasso penalty to adjust estimate's smoothness. Re-expressing the logarithm of the density estimator via a linear combination of Legendre polynomials, we can estimate parameters by maximizing the penalized log-likelihood function. Besides, we proposed an implementation strategy that builds on the coordinate decent algorithm, together with the Bayesian information criterion (BIC). / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-plfm	2.2.2	Functions for estimating probabilistic latent feature models with a disjunctive, conjunctive or additive mapping rule on (aggregated) binary three-way data. / GPL-2	linux-64, osx-64, win-64
r-pliable	1.1	Fits a pliable lasso model. For details see Tibshirani and Friedman (2018) <arXiv:1712.00484>. / GPL-3	linux-64, osx-64, win-64
r-plis	1.1	PLIS is a multiple testing procedure for testing several groups of hypotheses. Linear dependency is expected from the hypotheses within the same group and is modeled by hidden Markov Models. It is noted that, for PLIS, a smaller p value does not necessarily imply more significance because of dependency among the hypotheses. A typical application of PLIS is to analyze genome wide association studies datasets, where SNPs from the same chromosome are treated as a group and exhibit strong linear genomic dependency. / GPL-3	noarch
r-plm	1.7_0	A set of estimators and tests for panel data econometrics. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-pln	0.2_1	Performs bivariate composite likelihood and full information maximum likelihood estimation for polytomous logit-normit (graded logistic) item response theory (IRT) models. / GPL-3	linux-64, osx-64, win-64
r-plogr	0.2.0	A simple header-only logging library for C. Add 'LinkingTo: plogr' to 'DESCRIPTION', and '#include <plogr.h>' in your C modules to use it. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-plordprob	1.1	Multivariate ordered probit model, i.e. the extension of the scalar ordered probit model where the observed variables have dimension greater than one. Estimation of the parameters is done via maximization of the pairwise likelihood, a special case of the composite likelihood obtained as product of bivariate marginal distributions. The package uses the Fortran 77 subroutine SADMVN by Alan Genz, with minor adaptations made by Adelchi Azzalini in his mvnrmf package for evaluating the two-dimensional Gaussian integrals involved in the pairwise log-likelihood. Optimization of the latter objective function is performed via quasi-Newton box-constrained optimization algorithm, as implemented in nlminb. / GPL-2	linux-64, osx-64, win-64
r-plot.matrix	1.2	Visualizes a matrix object plainly as heatmap. It provides S3 functions to plot simple matrices and loading matrices. / GPL-3	noarch
r-plotcontour	0.1.0	This function plots a contour line with a user-defined probability and tightness of fit. / GPL-2	noarch
r-plotfunctions	1.3	When analyzing data, plots are a helpful tool for visualizing data and interpreting statistical models. This package provides a set of simple tools for building plots incrementally, starting with an empty plot region, and adding bars, data points, regression lines, error bars, gradient legends, density distributions in the margins, and even pictures. The package builds further on R graphics by simply combining functions and settings in order to reduce the amount of code to produce for the user. As a result, the package does not use formula input or special syntax, but can be used in combination with default R plot functions. Note: Most of the functions were part of the package 'itsadug', which is now split in two packages: 1. the package 'itsadug', which contains the core functions for visualizing and evaluating nonlinear regression models, and 2. the package 'plotfunctions', which contains more general plot functions. / GPL-2	noarch
r-plotly	4.9.0	Create interactive web graphics from 'ggplot2' graphs and/or a custom interface to the (MIT-licensed) JavaScript library 'plotly.js' inspired by the grammar of graphics. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-plotlygeoassets	0.0.2	Includes 'JavaScript' files that allow 'plotly' maps to render without an internet connection. / MIT	noarch
r-plotmcmc	2.0_0	Markov chain Monte Carlo diagnostic plots. The purpose of the package is to combine existing tools from the 'coda' and 'lattice' packages, and make it easy to adjust graphical details. / GPL-2	noarch
r-plotpc	1.0.4	Plot principal component histograms around a bivariate scatter plot. / GPL-3	noarch
r-plotregionhighlighter	1.0	Creates an envelope around a set of plotted points. The envelope is compact with a boundary that is continuous, smooth and convex. Each point is represented as a circle and the circles and connecting lines are the solution to the multiple pulley problem. This method can be used to highlight regions in a two-dimensional space. / GPL-2	noarch
r-plotrix	3.7_6	Lots of plots, various labeling, axis and color scaling functions. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-plotscale	0.1.6	Figures rendered on graphics devices are usually rescaled to fit pre-determined device dimensions. ‘plotscale’ implements the reverse: desired plot dimensions are specified and device dimensions are calculated to accommodate marginal material, giving consistent proportions for plot elements. Default methods support grid graphics such as lattice and ggplot. See example(‘devsize’) and vignette(‘plotscale’). / GPL-3	noarch
r-plotwidgets	0.4	Small self-contained plots for use in larger plots or to delegate plotting in other functions. Also contains a number of alternative color palettes and HSL color space based tools to modify colors or palettes. / GPL (>= 2.0)	noarch
r-plrasch	1.0	Fit Log Linear by Linear Association models and Rasch family models by pseudolikelihood estimation / GPL-2	noarch
r-plrmodels	1.1	This package provides statistical inference tools applied to Partial Linear Regression (PLR) models. Specifically, point estimation, confidence intervals estimation, bandwidth selection, goodness-of-fit tests and analysis of covariance are considered. Kernel-based methods, combined with ordinary least squares estimation, are used and time series errors are allowed. In addition, these techniques are also implemented for both parametric (linear) and nonparametric regression models. / GPL-3	noarch
r-pls	2.7_1	Multivariate regression methods Partial Least Squares Regression (PLSR), Principal Component Regression (PCR) and Canonical Powered Partial Least Squares (CPPLS). / GPL-2	linux-64, noarch, osx-64, win-32, win-64
r-plsbiplot1	0.1	Principal Component Analysis (PCA) biplots, Covariance monoplots and biplots, Partial Least Squares (PLS) biplots, Partial Least Squares for Generalized Linear Model (PLS-GLM) biplots, Sparse Partial Least Squares (SPLS) biplots and Sparse Partial Least Squares for Generalized Linear Model (SPLS-GLM) biplots. / GPL-2	noarch
r-plsdepot	0.1.17	plsdepot contains different methods for PLS analysis of one or two data tables such as Tucker’s Inter-Battery, NIPALS, SIMPLS, SIMPLS-CA, PLS Regression, and PLS Canonical Analysis. The main reference for this software is the awesome book (in French) ‘La Regression PLS: Theorie et Pratique’ by Michel Tenenhaus. / GPL-3	noarch
r-plsdof	0.2_9	The plsdof package provides Degrees of Freedom estimates for Partial Least Squares (PLS) Regression. Model selection for PLS is based on various information criteria (aic, bic, gmdl) or on cross-validation. Estimates for the mean and covariance of the PLS regression coefficients are available. They allow the construction of approximate confidence intervals and the application of test procedures. Further, cross-validation procedures for Ridge Regression and Principal Components Regression are available. / GPL-2	noarch
r-plugdensity	0.8_3	Kernel density estimation with global bandwidth selection via plug-in. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-plumber	0.4.6	Gives the ability to automatically generate and serve an HTTP API from R functions using the annotations in the R documentation around your functions. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-plus	1.0	Efficient procedures for fitting an entire regression sequences with different model types. / GPL-2	noarch
r-pluscode	0.1.0	Retrieves a 'pluscode' by inputting latitude and longitude. Includes additional functions to retrieve neighbouring 'pluscodes'. / GPL-2	noarch
r-plusser	0.4.0	plusser provides an API interface to Google so that posts, profiles and pages can be automatically retrieved. / GPL-3	noarch
r-plyr	1.8.4	A set of tools that solves a common set of problems: you need to break a big problem down into manageable pieces, operate on each piece and then put all the pieces back together. For example, you might want to fit a model to each spatial location or time point in your study, summarise data by panels or collapse high-dimensional arrays to simpler summary statistics. The development of 'plyr' has been generously supported by 'Becton Dickinson'. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-pmcmmr	4.3	Note, that the 'PMCMR' package is superseded by the novel 'PMCMRplus' package. The 'PMCMRplus' package contains all functions from 'PMCMR' and many more parametric and non-parametric multiple comparison procedures, one-factorial trend tests, as well as improved method functions, such as print, summary and plot. The 'PMCMR' package is no longer maintained, but kept for compatibility of reverse depending packages for some time. / GPL-3	noarch
r-pmml	2.0.0	The Predictive Model Markup Language (PMML) is an XML-based language which provides a way for applications to define machine learning, statistical and data mining models and to share models between PMML compliant applications. More information about the PMML industry standard and the Data Mining Group can be found at < http://www.dmg.org >. The generated PMML can be imported into any PMML consuming application, such as Zementis Predictive Analytics products, which integrate with web services, relational database systems and deploy natively on Hadoop in conjunction with Hive, Spark or Storm, as well as allow predictive analytics to be executed for IBM z Systems mainframe applications and real-time, streaming analytics platforms. The package isoform (used for anomaly detection) can be installed with devtools::install_github(Zelazny7/isoform). / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pmmltransformations	1.3.3	Allows for data to be transformed before using it to construct models. Builds structures to allow functions in the PMML package to output transformation details in addition to the model in the resulting PMML file. The Predictive Model Markup Language (PMML) is an XML-based language which provides a way for applications to define machine learning, statistical and data mining models and to share models between PMML compliant applications. More information about the PMML industry standard and the Data Mining Group can be found at < http://www.dmg.org >. The generated PMML can be imported into any PMML consuming application, such as Zementis Predictive Analytics products, which integrate with web services, relational database systems and deploy natively on Hadoop in conjunction with Hive, Spark or Storm, as well as allow predictive analytics to be executed for IBM z Systems mainframe applications and real-time, streaming analytics platforms. / GPL (>= 2.1)	noarch
r-pmr	1.2.5	Descriptive statistics (mean rank, pairwise frequencies, and marginal matrix), Analytic Hierarchy Process models (with Saaty's and Koczkodaj's inconsistencies), probability models (Luce models, distance-based models, and rank-ordered logit models) and visualization with multidimensional preference analysis for ranking data are provided. Current, only complete rankings are supported by this package. / GPL-2	noarch
r-pmsampsize	1.0.1	Computes the minimum sample size required for the development of a new multivariable prediction model using the criteria proposed by Riley et al. (2018) <doi: 10.1002/sim.7992>. pmsampsize can be used to calculate the minimum sample size for the development of models with continuous, binary or survival (time-to-event) outcomes. Riley et al. (2018) <doi: 10.1002/sim.7992> lay out a series of criteria the sample size should meet. These aim to minimise the overfitting and to ensure precise estimation of key parameters in the prediction model. / GPL-3	noarch
r-pmultinom	1.0.0	Implements multinomial CDF ($P(N_1 \leq n_1, \dots, N_k \leq n_k)$) and tail probabilities ($P(N_1 > n_1, \dots, N_k > n_k)$), as well as probabilities with both constraints ($P(l_1 < N_1 \leq u_1, \dots, l_k < N_k \leq u_k)$). Uses a method suggested by Bruce Levin (1981) <doi:10.1214/aos/1176345593>. / AGPL-3	noarch
r-png	0.1_7	This package provides an easy and simple way to read, write and display bitmap images stored in the PNG format. It can read and write both files and in-memory raw vectors. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-pnmtrem	1.3	An R package for Probit-Normal Marginalized Transition Random Effects Models / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pnn	1.0.1	The program pnn implements the algorithm proposed by Specht (1990). It is written in the R statistical language. It solves a common problem in automatic learning. Knowing a set of observations described by a vector of quantitative variables, we classify them in a given number of groups. Then, the algorithm is trained with this datasets and should guess afterwards the group of any new observation. This neural network has the main advantage to begin generalization instantaneously even with a small set of known observations. It is delivered with four functions (learn, smooth, perf and guess) and a dataset. The functions are documented with examples and provided with unit tests. / AGPL-3	noarch
r-pocrm	0.12	Provides functions to implement and simulate the partial order continual reassessment method (PO-CRM) of Wages, Conaway and O’Quigley (2011) <doi:10.1177/1740774511408748> for use in Phase I trials of combinations of agents. Provides a function for generating a set of initial guesses (skeleton) for the toxicity probabilities at each combination that correspond to the set of possible orderings of the toxicity probabilities specified by the user. / GPL-2	noarch
r-pod	1.1.4	This tool computes the probability of detection (POD) curve and the limit of detection (LOD), i.e. the number of copies of the target DNA sequence required to ensure a 95 % probability of detection (LOD95). Other quantiles of the LOD can be specified. This is a reimplement of the mathematical-statistical modelling of the validation of qualitative polymerase chain reaction (PCR) methods within a single laboratory as provided by the commercial tool ‘PROLab’ < http://quodata.de/ >. The modelling itself has been described by Uhlig et al. (2015) <doi:10.1007/s00769-015-1112-9>. / GPL-3	noarch
r-poet	2.0	Estimate large covariance matrices in approximate factor models by thresholding principal orthogonal complements. / GPL-2	noarch
r-poibin	1.3	Implementation of both the exact and approximation methods for computing the cdf of the Poisson binomial distribution. It also provides the pmf, quantile function, and random number generation for the Poisson binomial distribution. / GPL-2	linux-64, osx-64, win-64
r-poiclaclu	1.0.2	Implements the methods described in the paper, Witten (2011) Classification and Clustering of Sequencing Data using a Poisson Model, Annals of Applied Statistics 5(4) 2493-2518. / GPL-2	noarch
r-poilog	0.4	Functions for obtaining the density, random deviates and maximum likelihood estimates of the Poisson lognormal distribution and the bivariate Poisson lognormal distribution. / GPL-3	linux-64, osx-64, win-64
r-pointdensity	0.3.4	The function pointdensity returns a density count and the temporal average for every point in the original list. The dataframe returned includes four columns: lat, lon, count, and date_avg. The lat column is the original latitude data; the lon column is the original longitude data; the count is the density count of the number of points within a radius of radius*grid_size (the neighborhood); and the date_avg column includes the average date of each point in the neighborhood. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-poisbinnonnor	1.3.1	Generation of multiple count, binary and continuous variables simultaneously given the marginal characteristics and association structure. Throughout the package, the word ‘Poisson’ is used to imply count data under the assumption of Poisson distribution. / GPL-2 GPL-3	noarch
r-poisbinom	1.0.1	Provides the probability, distribution, and quantile functions and random number generator for the Poisson-Binomial distribution. This package relies on FFTW to implement the discrete Fourier transform, so that it is much faster than the existing implementation of the same algorithm in R. / GPL-2	linux-64, osx-64, win-64
r-poisdoublesamp	1.1	Functions to create confidence intervals for ratios of Poisson rates under misclassification using double sampling. / GPL-2	linux-64, osx-64, win-64
r-poisnonnor	1.6.1	Generation of count (assuming Poisson distribution) and continuous data (using Fleishman polynomials) simultaneously. / GPL-2 GPL-3	noarch
r-poisnor	1.3.1	Generates multivariate data with count and continuous variables with a pre-specified correlation matrix. The count and continuous variables are assumed to have Poisson and normal marginals, respectively. The data generation mechanism is a combination of the normal to anything principle and a connection between Poisson and normal correlations in the mixture. / GPL-2	noarch
r-poisson	1.0	Contains functions and classes for simulating, plotting and analysing homogeneous and non-homogenous Poisson processes. / GPL-2	noarch
r-poisson.glm.mix	1.2	High dimensional mixtures of Poisson Generalized Linear models with three different parameterizations of Poisson means are considered. Moreover, partitioning the response variables into a set of blocks is possible. The package estimates parameters via EM algorithm. For an efficient initialization, a random splitting small-EM is introduced. / GPL-2	noarch
r-poissonpca	1.0.2	For a multivariate dataset with independent Poisson measurement error, calculates principal components of transformed latent Poisson means. T. Kenney, T. Huang, H. Gu (2019) <arXiv:1904.11745>. / GPL-3	linux-64, osx-64, win-64
r-poissonseq	1.1.2	This package implements a method for normalization, testing, and false discovery rate estimation for RNA-sequencing data. The description of the method is in Li J, Witten DM, Johnstone I, Tibshirani R (2012). Normalization, testing, and false discovery rate estimation for RNA-sequencing data. Biostatistics 13(3): 523-38. We estimate the sequencing depths of experiments using a new method based on Poisson goodness-of-fit statistic, calculate a score statistic on the basis of a Poisson log-linear model, and then estimate the false discovery rate using a modified version of permutation plug-in method. A more detailed instruction as well as sample data is available at http://www.stanford.edu/~junli07/research.html . In this version, we changed the way of calculating log foldchange for two-class data. The FDR estimation part remains unchanged. / GPL-2	noarch
r-poistweedie	1.0	Simulation of models Poisson-Tweedie. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-poker	0.8.8	Type testRoundOfPoker() to demonstrate the game of Texas Hold ~Em poker. Rotate the dealer button, deal cards, rank each hand, compare ranks, break ties (if necessary), determine the winner, output a textual summary, and output a graphical user interface. / GPL-2	noarch
r-polidata	0.1.0	This package provides easy access to various political data APIs directly from R. For example, you can access Google Civic Information API < https://developers.google.com/civic-information/ > or Sunlight Congress API < https://sunlightlabs.github.io/congress/ > for US Congress data, and POPONG API < http://data.popong.com/ > for South Korea National Assembly data. / MIT	noarch
r-politicaldata	0.1.3	Provides useful functions for obtaining commonly-used data in political analysis and political science, including from sources such as the Comparative Agendas Project < https://www.comparativeagendas.net/ >, which provides data on politics and policy from 20 countries, the MIT Election and Data Science Lab < https://www.electionlab.mit.edu/ >, and FiveThirtyEight < https://www.FiveThirtyEight.com/ >. / MIT	noarch
r-pollstr	2.0.1	Client for the HuffPost Pollster API, which provides access to U.S. polls on elections and political opinion. / GPL-2	noarch
r-polspline	1.1.14	Routines for the polynomial spline fitting routines hazard regression, hazard estimation with flexible tails, logspline, lspec, polyclass, and polymars, by C. Kooperberg and co-authors. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-polyaaeppli	2.0	Functions for evaluating the mass density, cumulative distribution function, quantile function and random variate generation for the Polya-Aeppli distribution, also known as the geometric compound Poisson distribution. / GPL-2	noarch
r-polyclip	1.10	R port of Angus Johnson's open source library Clipper. Performs polygon clipping operations (intersection, union, set minus, set difference) for polygonal regions of arbitrary complexity, including holes. Computes offset polygons (spatial buffer zones, morphological dilations, Minkowski dilations) for polygonal regions and polygonal lines. Computes Minkowski Sum of general polygons. There is a function for removing self-intersections from polygon data. / BSL	linux-64, osx-64, win-64
r-polycor	0.7.1	Computes polychoric and polyserial correlations by quick two-step methods or ML, optionally with standard errors; tetrachoric and biserial correlations are special cases. / GPL-2	noarch
r-polycub	0.7.1	Numerical integration of continuously differentiable functions f(x,y) over simple closed polygonal domains. The following cubature methods are implemented: product Gauss cubature (Sommariva and Vianello, 2007, < doi:10.1007/s10543-007-0131-2 >), the simple two-dimensional midpoint rule (wrapping 'spatstat' functions), adaptive cubature for radially symmetric functions via line integrate() along the polygon boundary (Meyer and Held, 2014, < doi:10.1214/14-AOAS743 >, Supplement B), and integration of the bivariate Gaussian density based on polygon triangulation. For simple integration along the axes, the 'cubature' package is more appropriate. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-polyfreqs	1.0.2	Implements a Gibbs sampling algorithm to perform Bayesian inference on biallelic SNP frequencies, genotypes and heterozygosity (observed and expected) in a population of autopolyploids. See the published paper in Molecular Ecology Resources: Blischak et al. (2016) <doi:10.1111/1755-0998.12493>. / GPL-2	linux-64, osx-64, win-64
r-polylabelr	0.1.0	A wrapper around the C library 'polylabel' from 'Mapbox', providing an efficient routine for finding the approximate pole of inaccessibility of a polygon, which usually serves as an excellent candidate for labeling of a polygon. / MIT	linux-64, osx-64, win-64
r-polynom	1.4_0	A collection of functions to implement a class for univariate polynomial manipulations. / GPL-2	noarch
r-polynomf	2.0_2	Implements univariate polynomial operations in R, including polynomial arithmetic, finding zeros, plotting, and some operations on lists of polynomials. / GPL-2	linux-64, osx-64, win-64
r-polypatex	0.9.2	Functions to perform paternity exclusion via allele matching, in autopolyploid species having ploidy 4, 6, or 8. The marker data used can be genotype data (copy numbers known) or 'allelic phenotype data' (copy numbers not known). / GPL-3	noarch
r-polysat	1.7_4	A collection of tools to handle microsatellite data of any ploidy (and samples of mixed ploidy) where allele copy number is not known in partially heterozygous genotypes. It can import and export data in ABI 'GeneMapper', 'Structure', 'ATetra', 'Tetrasat'/'Tetra', 'GenoDive', 'SPAGeDi', 'POPDIST', 'STRand', and binary presence/absence formats. It can calculate pairwise distances between individuals using a stepwise mutation model or infinite alleles model, with or without taking ploidies and allele frequencies into account. These distances can be used for the calculation of clonal diversity statistics or used for further analysis in R. Allelic diversity statistics and Polymorphic Information Content are also available. polysat can assist the user in estimating the ploidy of samples, and it can estimate allele frequencies in populations, calculate pairwise or global differentiation statistics based on those frequencies, and export allele frequencies to 'SPAGeDi' and 'adeget'. Functions are also included for assigning alleles to isoloci in cases where one pair of microsatellite primers amplifies alleles from two or more independently segregating isoloci. polysat is described by Clark and Jasieniuk (2011) <doi:10.1111/j.1755-0998.2011.02985.x> and Clark and Schreier (2017) <doi:10.1111/1755-0998.12639>. / GPL-2	linux-64, osx-64, win-64
r-polysegratio	0.2_5	Perform classic chi-squared tests and Ripol et al(1999) binomial confidence interval approach for autopolyploid dominant markers. Also, dominant markers may be generated for families of offspring where either one or both of the parents possess the marker. Missing values and misclassified markers may be generated at random. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-polytrend	1.2	This algorithm classifies the trends into linear, quadratic, cubic, concealed and no-trend types. The concealed trends are those trends that possess quadratic or cubic forms, but the net change from the start of the time period to the end of the time period hasn't been significant. The no-trend category includes simple linear trends with statistically in-significant slope coefficient. / GPL-2	noarch
r-pomaspu	1.0.0	POM-aSPU test evaluates an association between an ordinal response and multiple phenotypes, for details see Kim and Pan (2017) <DOI:10.1002/gepi.22033>. / GPL-3	linux-64, osx-64, win-64
r-pomdp	0.9.1	Provides an interface to pomdp-solve, a solver for Partially Observable Markov Decision Processes (POMDP). The package enables the user to simply define all components of a POMDP model and solve the problem using several methods. The package also contains functions to analyze and visualize the POMDP solutions (e.g., the optimal policy). / GPL-3	linux-64, osx-64
r-pomic	1.0.4	Calculations of an information criterion are proposed to check the quality of simulations results of Agent-based models (ABM/IBM) or other non-linear rule-based models. The POMDEV measure (Pattern Oriented Modelling Deviance) is based on the Kullback-Leibler divergence and likelihood theory. It basically indicates the deviance of simulation results from field observations. Once POMDEV scores and metropolis-hasting sampling on different model versions are effectuated, POMIC scores (Pattern Oriented Modelling Information Criterion) can be calculated. This method could be further developed to incorporate multiple patterns assessment. Piou C, U Berger and V Grimm (2009) <doi:10.1016/j.ecolmodel.2009.05.003>. / GPL-2	noarch
r-pomp	2.3	Tools for data analysis with partially observed Markov process (POMP) models (also known as stochastic dynamical systems, hidden Markov models, and nonlinear, non-Gaussian, state-space models). The package provides facilities for implementing POMP models, simulating them, and fitting them to time series data by a variety of frequentist and Bayesian methods. It is also a versatile platform for implementation of inference methods for general POMP models. / GPL-3	linux-64, osx-64, win-64
r-pooh	0.3.2	Finds equivalence classes corresponding to a symmetric relation or undirected graph. Finds total order consistent with partial order or directed graph (so-called topological sort). / MIT	linux-64, osx-64, win-64
r-pool	0.1.4	Enables the creation of object pools, which make it less computationally expensive to fetch a new object. Currently the only supported pooled objects are 'DBI' connections. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pooledmeangroup	1.0	Calculates the pooled mean group (PMG) estimator for dynamic panel data models, as described by Pesaran, Shin and Smith (1999) <doi:10.1080/01621459.1999.10474156>. / GPL-2	noarch
r-poolfstat	1.1.0	Functions for the computation of F-statistics from Pool-Seq data in population genomics studies. The package also includes several utilities to manipulate Pool-Seq data stored in standard format ('vcf' or 'rsync' files generated by the the 'PoPoolation' software) and perform conversion to alternative format (as used in the 'BayPass' and 'SelEstim' software). / GPL-2	noarch
r-pop	0.1	Population dynamic models underpin a range of analyses and applications in ecology and epidemiology. The various approaches for analysing population dynamics models (MPMs, IPMs, ODEs, POMP, PVA) each require the model to be defined in a different way. This makes it difficult to combine different modelling approaches and data types to solve a given problem. 'pop' aims to provide a flexible and easy to use common interface for constructing population dynamic models and enabling to them to be fitted and analysed in lots of different ways. / MIT	noarch
r-pop.wolf	0.1	Simulate the dynamic of wolf populations using a specific Individual-Based Model (IBM) compiled in C. / GPL-3	linux-64, osx-64, win-64
r-popbio	2.4.4	Construct and analyze projection matrix models from a demography study of marked individuals classified by age or stage. The package covers methods described in Matrix Population Models by Caswell (2001) and Quantitative Conservation Biology by Morris and Doak (2002). / GPL-3	noarch
r-popdemog	1.0.3	Plot demographic graphs for single/multiple populations from coalescent simulation program input. Currently, this package can support the 'ms', 'msHot', 'MaCS', 'msprime', 'SCRM', and 'Cosi2' simulation programs. It does not check the simulation program input for correctness, but assumes the simulation program input has been validated by the simulation program. More features will be added to this package in the future, please check the 'GitHub' page for the latest updates: < https://github.com/YingZhou001/POPdemog >. / GPL-2	noarch
r-popgenkit	1.0	There are two main purposes to this package. The first is to allow batch conversion of Genepop (Rousset 2008) input files for use with Arlequin (Excoffier and Lischer 2010), which has a simple GUI to analyze batch files. Two commonly used simulation software, BottleSim (Kuo & Janzen 2003) and Easy-pop (Balloux 2001) produce Genepop output files that can be analyzed this way. There are also functions to convert to and from BottleSim format, to quickly produce allele frequency tables or to convert a file directly for use in ordination analyses (e.g. principal component analysis). This package also includes functions to calculate allele rarefaction curves, confidence intervals on heterozygosity and allelic richness with resampling strategies (bootstrap and jackknife). / GPL-2	noarch
r-popkin	1.2.2	Provides functions to estimate the kinship matrix of individuals from a large set of biallelic SNPs, and extract inbreeding coefficients and the generalized FST (Wright's fixation index). Method described in Ochoa and Storey (2016) <doi:10.1101/083923>. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-popkorn	0.3_0	Provides a suite of tools for various methods of estimating confidence intervals for the mean of selected populations. / MIT	noarch
r-poprange	1.1.3	Runs a forward genetic simulator / MIT	noarch
r-popreconstruct	1.0_5	Implements the Bayesian hierarchical model described by Wheldon, Raftery, Clark and Gerland (see: <doi:10.1080/01621459.2012.737729>) for simultaneously estimating age-specific population counts, fertility rates, mortality rates and net international migration flows, at the national level. / GPL-3	noarch
r-poptrend	0.1.0	Functions to estimate and plot smooth or linear population trends, or population indices, from animal or plant count survey data. / GPL-3	noarch
r-population	0.2	Run population simulations using an Individual-Based Model (IBM) compiled in C. / GPL-3	linux-64, osx-64, win-64
r-portfolio	0.4_7	Classes for analysing and implementing equity portfolios. / GPL-2	noarch
r-portsort	0.1.0	Designed to aid both academic researchers and asset managers in conducting factor based portfolio sorts. Provides functionality to sort assets into portfolios for up to three factors via a conditional or unconditional sorting procedure. / GPL-2	noarch
r-posi	1.0	In linear LS regression, calculate for a given design matrix the multiplier K of coefficient standard errors such that the confidence intervals [b - K*SE(b), b + K*SE(b)] have a guaranteed coverage probability for all coefficient estimates b in any submodels after performing arbitrary model selection. / GPL-3	noarch
r-postcodesior	0.1.1	Free UK geocoding using data from Office for National Statistics. It is using several functions to get information about post codes, outward codes, reverse geocoding, nearest post codes/outward codes, validation, or randomly generate a post code. API wrapper around < https://postcodes.io >. / GPL-3	noarch
r-postinfectious	0.1.0	Functions to estimate the incubation period distribution of post-infectious syndrome which is defined as the time between the symptom onset of the antecedent infection and that of the post-infectious syndrome. / GPL-2	noarch
r-postlogic	0.1.0	Provides adds postfix and infix logic operators for if, then, unless, and otherwise. / GPL-2	noarch
r-pot	1.1_7	Some functions useful to perform a Peak Over Threshold analysis in univariate and bivariate cases, see Beirlant et al. (2004) <doi:10.1002/0470012382>. A user's guide is available. / GPL-2	linux-64, osx-64, win-64
r-potts	0.5_8	Do Markov chain Monte Carlo (MCMC) simulation of Potts models (Potts, 1952, <doi:10.1017/S0305004100027419>), which are the multi-color generalization of Ising models (so, as a special case, also simulates Ising models). Use the Swendsen-Wang algorithm (Swendsen and Wang, 1987, <doi:10.1103/PhysRevLett.58.86>) so MCMC is fast. Do maximum composite likelihood estimation of parameters (Besag, 1975, <doi:10.2307/2987782>, Lindsay, 1988, <doi:10.1090/conm/080>). / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-power	1.0.7	Functions for the computation of power and level tables for hypothesis tests, in Latex format, functions to build explanatory graphs for studying power of test statistics. / GPL-2	linux-64, osx-64, win-64
r-poweranalysis	0.2.1	Basic functions for power analysis and effect size calculation. / GPL-2	noarch
r-powercomprisk	1.0.1	A power analysis tool for jointly testing the cause-1 cause-specific hazard and the any-cause hazard with competing risks data. / GPL-2	noarch
r-powerfulmaxeigenpair	0.1.0	An implementation for using powerful algorithm to compute the maximal eigenpair of Hermitizable tridiagonal matrices in R. It provides two algorithms to find the maximal and the next to maximal eigenpairs under the tridiagonal matrix. Besides, it also provides two auxiliary algorithms to generate tridiagonal matrix and solve the linear equation by Thomas algorithm. Several examples are included in the vignettes to illustrate the usage of the functions. / MIT	noarch
r-powerlaw	0.70.2	An implementation of maximum likelihood estimators for a variety of heavy tailed distributions, including both the discrete and continuous power law distributions. Additionally, a goodness-of-fit based approach is used to estimate the lower cut-off for the scaling region. / GPL-2 GPL-3	noarch
r-powerlmm	0.4.0	Calculate power for the ‘time x treatment’ effect in two- and three-level multilevel longitudinal studies with missing data. Both the third-level factor (e.g. therapists, schools, or physicians), and the second-level factor (e.g. subjects), can be assigned random slopes. Studies with partially nested designs, unequal cluster sizes, unequal allocation to treatment arms, and different dropout patterns per treatment are supported. For all designs power can be calculated both analytically and via simulations. The analytical calculations extends the method described in Galbraith et al. (2002) <doi:10.1016/S0197-2456(02)00205-2>, to three-level models. Additionally, the simulation tools provides flexible ways to investigate bias, Type I errors and the consequences of model misspecification. / GPL-3	noarch
r-powermediation	0.2.9	Functions to calculate power and sample size for testing (1) mediation effects; (2) the slope in a simple linear regression; (3) odds ratio in a simple logistic regression; (4) mean change for longitudinal study with 2 time points; (5) interaction effect in 2-way ANOVA; and (6) the slope in a simple Poisson regression. / GPL-2	noarch
r-powernormal	1.2.0	Miscellaneous functions for a descriptive analysis and initial Bayesian and classical inference for the power parameter of the the Power Normal (PN) distribution. This miscellaneous will be extend for more distributions into the power family and the three-parameter model. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-powerpkg	1.5	(1) To estimate the power of testing for linkage using an affected sib pair design, as a function of the recurrence risk ratios. We will use analytical power formulae as implemented in R. These are based on a Mathematica notebook created by Martin Farrall. (2) To examine how the power of the transmission disequilibrium test (TDT) depends on the disease allele frequency, the marker allele frequency, the strength of the linkage disequilibrium, and the magnitude of the genetic effect. We will use an R program that implements the power formulae of Abel and Muller-Myhsok (1998). These formulae allow one to quickly compute power of the TDT approach under a variety of different conditions. This R program was modeled on Martin Farrall's Mathematica notebook. / GPL-2	noarch
r-powersurvepi	0.1.0	Functions to calculate power and sample size for testing main effect or interaction effect in the survival analysis of epidemiological studies (non-randomized studies), taking into account the correlation between the covariate of the interest and other covariates. Some calculations also take into account the competing risks and stratified analysis. This package also includes a set of functions to calculate power and sample size for testing main effect in the survival analysis of randomized clinical trials. / GPL-2	noarch
r-powerupr	1.0.4	Includes tools to calculate statistical power, minimum detectable effect size (MDES), MDES difference (MDESd), and minimum required sample size for various multilevel randomized experiments with continuous outcomes. Some of the functions can assist with planning two- and three-level cluster-randomized trials (CRTs) sensitive to multilevel moderation and mediation (2-1-1, 2-2-1, and 3-2-1). See 'PowerUp!' Excel series at < https://www.causalevaluation.org/ >. / GPL-3	noarch
r-pp	0.6.2	The PP package includes estimation of (MLE, WLE, MAP, EAP, ROBUST) person parameters for the 1,2,3,4-PL model and the GPCM (generalized partial credit model). The parameters are estimated under the assumption that the item parameters are known and fixed. The package is useful e.g. in the case that items from an item pool / item bank with known item parameters are administered to a new population of test-takers and an ability estimation for every test-taker is needed. / GPL-3	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pp3	1.2	Exploratory projection pursuit is a method to discovers structure in multi-variate data. At heart this package uses a projection index to evaluate how interesting a specific three-dimensional projection of multivariate data (with more than three dimensions) is. Typically, the main structure finding algorithm starts at a random projection and then iteratively changes the projection direction to move to a more interesting one. In other words, the projection index is maximised over the projection direction to find the most interesting projection. This maximum is, though, a local maximum. So, this code has the ability to restart the algorithm from many different starting positions automatically. Routines exist to plot a density estimate of projection indices over the runs, this enables the user to obtain an idea of the distribution of the projection indices, and, hence, which ones might be interesting. Individual projection solutions, including those identified as interesting, can be extracted and plotted individually. The package can make use of the mclapply() function to execute multiple runs in parallel to speed up index discovery. Projection pursuit is similar to independent component analysis. This package uses a projection index that maximises an entropy measure to look for projections that exhibit non-normality, and operates on sphered data. Hence, information from this package is different from that obtained from principal components analysis, but the rationale behind both methods is similar. Nason, G. P. (1995) <doi:10.2307/2986135>. / GPL-2	linux-64, osx-64, win-64
r-ppcc	1.1	Calculates the Probability Plot Correlation Coefficient (PPCC) between a continuous variable X and a specified distribution. The corresponding composite hypothesis test that was first introduced by Filliben (1975) <doi: 10.1080/00401706.1975.10489279> can be performed to test whether the sample X is element of either the Normal, log-Normal, Exponential, Uniform, Cauchy, Logistic, Generalized Logistic, Gumbel (GEVI), Weibull, Generalized Extreme Value, Pearson III (Gamma 2), Mielke's Kappa, Rayleigh or Generalized Logistic Distribution. The PPCC test is performed with a fast Monte-Carlo simulation. / GPL-3	linux-64, osx-64, win-64
r-ppcor	1.1	Calculates partial and semi-partial (part) correlations along with p-value. / GPL-2	noarch
r-ppls	1.6_1	Contains linear and nonlinear regression methods based on Partial Least Squares and Penalization Techniques. Model parameters are selected via cross-validation, and confidence intervals and tests for the regression coefficients can be conducted via jackknifing. / GPL-2	noarch
r-ppmr	1.0	Efficient statistical inference of two-sample MR (Mendelian Randomization) analysis. It can account for the correlated instruments and the horizontal pleiotropy, and can provide the accurate estimates of both causal effect and horizontal pleiotropy effect as well as the two corresponding p-values. There are two main functions in the 'PPMR' package. One is PMR_individual() for individual level data, the other is PMR_summary() for summary data. / GPL-3	linux-64, osx-64, win-64
r-pps	0.94	The pps package contains functions to select samples using PPS (probability proportional to size) sampling. It also includes a function for stratified simple random sampling, a function to compute joint inclusion probabilities for Sampford's method of PPS sampling, and a few utility functions. The user's guide pps-ug.pdf is included. / GPL-2	noarch

Name	Version	Summary/License	Platforms
r-pqantimalarials	0.2	This package allows users to calculate the number of under-five child deaths caused by consumption of poor quality antimalarials across 39 sub-Saharan nations. The package supports one function, that starts an interactive web tool created using the shiny R package. The web tool runs locally on the user's machine. The web tool allows users to set input parameters (prevalence of poor quality antimalarials, case fatality rate of children who take poor quality antimalarials, and sample size) which are then used to perform an uncertainty analysis following the Latin hypercube sampling scheme. Users can download the output figures as PDFs, and the output data as CSVs. Users can also download their input parameters for reference. This package was designed to accompany the analysis presented in: J. Patrick Renschler, Kelsey Walters, Paul Newton, Ramanan Laxminarayan Estimated under-five deaths associated with poor-quality antimalarials in sub-Saharan Africa, 2014. Paper submitted. / GPL-3	noarch
r-pqlseq	1.1	An efficient tool designed for differential analysis of large-scale RNA sequencing (RNAseq) data and Bisulfite sequencing (BSseq) data in the presence of individual relatedness and population structure. 'PQLseq' first fits a Generalized Linear Mixed Model (GLMM) with adjusted covariates, predictor of interest and random effects to account for population structure and individual relatedness, and then performs Wald tests for each gene in RNAseq or site in BSseq. / GPL-2	linux-64, osx-64, win-64
r-pracma	2.2.5	Provides a large number of functions from numerical analysis and linear algebra, numerical optimization, differential equations, time series, plus some well-known special mathematical functions. Uses 'MATLAB' function names where appropriate to simplify porting. / GPL-3	noarch
r-practools	1.2	Functions and datasets to support Valliant, Dever, and Kreuter, "Practical Tools for Designing and Weighting Survey Samples" (2nd edition, 2018). Contains functions for sample size calculation for survey samples using stratified or clustered one-, two-, and three-stage sample designs. Other functions compute variance components for multistage designs and sample sizes in two-phase designs. A number of example data sets are included. / GPL-2	noarch
r-pragma	0.1.3	pragma allows for the use of pragma (also sometimes called directives or keywords. These allow assigning arbitrary functionality to a word without requiring the standard function call syntax i.e. with parens. / GPL-2	noarch
r-prais	1.1.1	The Prais-Winsten estimator (Prais & Winsten, 1954) takes into account AR(1) serial correlation of the errors in a linear regression model. The procedure recursively estimates the coefficients and the error autocorrelation of the specified model until sufficient convergence of the AR(1) coefficient is attained. / GPL-2	noarch
r-praise	1.0.0	Build friendly R packages that praise their users if they have done something good, or they just need it to feel better. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-praktikum	0.1	Kasulikud funktsioonid kvantitatiivsete mudelite kursuse (SHPH.00.004) jaoks / GPL-2	noarch
r-praznik	6.0.0	A collection of feature selection filters performing greedy optimisation of mutual information-based usefulness criteria, inspired by the overview by Brown, Pocock, Zhao and Lujan (2012) < http://www.jmlr.org/papers/v13/brown12a.html >. Implements, among other, minimum redundancy maximal relevancy ('mRMR') method by Peng, Long and Ding (2005) <doi:10.1109/TPAMI.2005.159>; joint mutual information ('JMI') method by Yang and Moody (1999) < http://papers.nips.cc/paper/1779-data-visualization-and-feature-selection-new-algorithms-for-nongaussian-data >; double input symmetrical relevance ('DISR') method by Meyer and Bontempi (2006) <doi:10.1007/11732242_9> as well as joint mutual information maximisation ('JMIM') method by Bennasar, Hicks and Setchi (2015) <doi:10.1016/j.eswa.2015.07.007>. / GPL-3	linux-64, osx-64, win-64
r-prclust	1.3	Clustering is unsupervised and exploratory in nature. Yet, it can be performed through penalized regression with grouping pursuit. In this package, we provide two algorithms for fitting the penalized regression-based clustering (PRclust) with non-convex grouping penalties, such as group truncated lasso, MCP and SCAD. One algorithm is based on quadratic penalty and difference convex method. Another algorithm is based on difference convex and ADMM, called DC-ADD, which is more efficient. Generalized cross validation and stability based method were provided to select the tuning parameters. Rand index, adjusted Rand index and Jaccard index were provided to estimate the agreement between estimated cluster memberships and the truth. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-precisesums	0.3	Most of the time floating point arithmetic does approximately the right thing. When adding sums or having products of numbers that greatly differ in magnitude, the floating point arithmetic may be incorrect. This package implements the Kahan (1965) sum <doi:10.1145/363707.363723>, Neumaier (1974) sum <doi:10.1002/zamm.19740540106>, pairwise-sum (adapted from 'NumPy', See Castaldo (2008) <doi:10.1137/070679946> for a discussion of accuracy), and arbitrary precision sum (adapted from the fsum in 'Python'; Shewchuk (1997) < http://www.cs.berkeley.edu/~jrs/papers/robustr.pdf >). In addition, products are changed to long double precision for accuracy, or changed into a log-sum for accuracy. / GPL-2	linux-64, osx-64, win-64
r-prediction	0.3.14	A one-function package containing 'prediction()', a type-safe alternative to 'predict()' that always returns a data frame. The 'summary()' method provides a data frame with average predictions, possibly over counterfactual versions of the data (a la the 'margins' command in 'Stata'). Marginal effect estimation is provided by the related package, 'margins' < https://cran.r-project.org/package=margins >. The package currently supports common model types (e.g., lm, glm) from the 'stats' package, as well as numerous other model classes from other add-on packages. See the README or main package documentation page for a complete listing. / MIT	noarch
r-predictiveregression	0.1_4	Three prediction algorithms described in the paper On-line predictive linear regression Annals of Statistics 37, 1566 - 1590 (2009) / file LICENSE (Restricts use)	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-predkmeans	0.1.0	Implements the predictive k-means method for clustering observations, using a mixture of experts model to allow covariates to influence cluster centers. Motivated by air pollution epidemiology settings, where cluster membership needs to be predicted across space. Includes functions for predicting cluster membership using spatial splines and principal component analysis (PCA) scores using either multinomial logistic regression or support vector machines (SVMs). For method details see Keller et al. (2017) <doi:10.1214/16-AOAS992>. / GPL-3	linux-64, osx-64, win-64
r-predmixcor	1.1.1	train_predict_mix predicts the binary response with binary features / GPL-2	noarch
r-preknitposthtmlrender	0.1.0	Dynamize headers or R code within 'Rmd' files to prevent proliferation of 'Rmd' files for similar reports. Add in external HTML document within 'rmarkdown' rendered HTML doc. / GPL-2	noarch
r-preputils	1.0.2	Miscellaneous small utilities are provided to mitigate issues with messy, inconsistent or high dimensional data and help for preprocessing and preparing analyses. / GPL-3	noarch
r-prereg	0.4.0	Provides a collection of templates to author preregistration documents for scientific studies in PDF format. / GPL-3	noarch
r-presenceabsence	1.1.9	This package provides a set of functions useful when evaluating the results of presence-absence models. Package includes functions for calculating threshold dependent measures such as confusion matrices, pcc, sensitivity, specificity, and Kappa, and produces plots of each measure as the threshold is varied. It will calculate optimal threshold choice according to a choice of optimization criteria. It also includes functions to plot the threshold independent ROC curves along with the associated AUC (area under the curve). / Unlimited	noarch
r-prettyb	0.2.1	Drop-in replacements for standard base graphics functions. The replacements are prettier versions of the originals. / GPL-2 GPL-3	noarch
r-prettycode	1.0.2	Replace the standard print method for functions with one that performs syntax highlighting, using ANSI colors, if the terminal supports them. / MIT	noarch
r-prettydoc	0.3.0	Creating tiny yet beautiful documents and vignettes from R Markdown. The package provides the 'html_pretty' output format as an alternative to the 'html_document' and 'html_vignette' engines that convert R Markdown into HTML pages. Various themes and syntax highlight styles are supported. / Apache License (>= 2.0)	noarch
r-prettygraphs	2.1.6	Simple and crisp publication-quality graphics for the ExPosition family of packages. See An ExPosition of the Singular Value Decomposition in R (Beaton et al 2014) <doi:10.1016/j.csda.2013.11.006>. / GPL-2	noarch
r-prettymapr	0.2.2	Automates the process of creating a scale bar and north arrow in any package that uses base graphics to plot in R. Bounding box tools help find and manipulate extents. Finally, there is a function to automate the process of setting margins, plotting the map, scale bar, and north arrow, and resetting graphic parameters upon completion. / GPL-2	noarch
r-prettyr	2.2.3	Functions for conventionally formatting descriptive stats, reshaping data frames and formatting R output as HTML. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-prettyunits	1.0.2	Pretty, human readable formatting of quantities. Time intervals: 1337000 -> 15d 11h 23m 20s. Vague time intervals: 2674000 -> about a month ago. Bytes: 1337 -> 1.34 kB. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-prevederer	0.0.1	Easy and efficient access to the API provided by ‘Prevedere’, an industry insights and predictive analytics company. Query and download indicators, models and workbenches built with ‘Prevedere’ for further analysis and reporting < https://www.prevedere.com/ >. / MIT	noarch
r-primefactr	0.1.1	Use Prime Factorization for simplifying computations, for instance for ratios of large factorials. / GPL-3	noarch
r-primes	0.1.0	Functions to test whether a number is prime and generate the prime numbers within a specified range. Based around an implementation of Wilson’s theorem for testing for an integer’s primality. / MIT	linux-64, osx-64, win-64
r-primme	3.0.0	R interface to PRIMME, a C library for computing a few eigenvalues and their corresponding eigenvectors of a real symmetric or complex Hermitian matrix. It can also compute singular values and vectors of a square or rectangular matrix. It can find largest, smallest, or interior singular/eigenvalues and can use preconditioning to accelerate convergence. / GPL-3	linux-64, osx-64
r-princurve	2.1.4	Fitting a principal curve to a data matrix in arbitrary dimensions. Hastie and Stuetzle (1989) <doi:10.2307/2289936>. / GPL-2	linux-64, osx-64, win-64
r-prinsimp	0.8.8	Provides capabilities beyond principal components analysis to focus on finding structure in low variability subspaces. Constructs and plots simple basis vectors for pre-defined and user-defined measures of simplicity. / AGPL-3	noarch
r-printr	0.1	Extends the S3 generic function knit_print() in ‘knitr’ to automatically print some objects using an appropriate format such as Markdown or LaTeX. For example, data frames are automatically printed as tables, and the help() pages can also be rendered in ‘knitr’ documents. / GPL-3	noarch
r-priogene	0.99.0	In gene sequencing methods, the topological features of protein-protein interaction (PPI) networks are often used, such as ToppNet < https://toppgene.cchmc.org >. In this study, a candidate gene prioritization method was proposed for non-communicable diseases considering disease risks transferred between genes in weighted disease PPI networks with weights for nodes and edges based on functional information. / Artistic-2.0	noarch
r-prioritizrdata	0.2.2	Conservation planning data sets for learning how to use the ‘prioritizr’ package < https://CRAN.R-project.org/package=prioritizr >. / GPL-3	noarch
r-prioritylasso	0.2.2	Fits successive Lasso models for several blocks of (omics) data with different priorities and takes the predicted values as an offset for the next block. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-prism.forecast	0.1.6	Implements Penalized Regression with Inferred Seasonality Module (PRISM) to generate forecast estimation of weekly unemployment initial claims using ‘Google Trends’ data. It includes required data and tools for backtesting the performance in 2007-2016. / GPL-2	noarch
r-prithulib	1.0.2	Enables user to perform the following: 1. Roll ‘n’ number of die/dice (roll()). 2. Toss ‘n’ number of coin(s) (toss()). 3. Play the game of Rock, Paper, Scissors. 4. Choose ‘n’ number of card(s) from a pack of 52 playing cards (Joker optional). / GPL-3	noarch
r-privatelr	1.2.2	Implements two differentially private algorithms for estimating L2-regularized logistic regression coefficients. A randomized algorithm F is epsilon-differentially private (C. Dwork, Differential Privacy, ICALP 2006 <DOI:10.1007/11681878_14>), if $ \log(P(F(D) \text{ in } S)) - \log(P(F(D') \text{ in } S)) \leq \epsilon$ for any pair D, D’ of datasets that differ in exactly one record, any measurable set S, and the randomness is taken over the choices F makes. / GPL-2	noarch
r-prnsamplr	0.1.0	Survey sampling using permanent random numbers (PRN’s). A solution to the problem of unknown overlap between survey samples, which leads to a low precision in estimates when the survey is repeated or combined with other surveys. The PRN solution is to supply the U(0, 1) random numbers to the sampling procedure, instead of having the sampling procedure generate them. In Lindblom (2014) <doi:10.2478/jos-2014-0047>, and therein cited articles, it is shown how this is carried out and how it improves the estimates. This package supports two common fixed-size sampling procedures (simple random sampling and probability-proportional-to-size sampling) and includes a function for transforming the PRN’s in order to control the sample overlap. / MIT	noarch
r-pro	0.1.1	Optogenetics is a new tool to study neuronal circuits that have been genetically modified to allow stimulation by flashes of light. This package implements the methodological framework, Point-process Response model for Optogenetics (PRO), for analyzing data from these experiments. This method provides explicit nonlinear transformations to link the flash point-process with the spiking point-process. Such response functions can be used to provide important and interpretable scientific insights into the properties of the biophysical process that governs neural spiking in response to optogenetic stimulation. / GPL-2	noarch
r-probmod	0.2.1	Contains functions that are useful for probing moderation effects (or interactions) including techniques such as pick-a-point (also known as spotlight analysis) and Johnson-Neyman (also known as floodlight analysis). Plot function is also provided to facilitate visualization of results from each of these techniques. / GPL-3	noarch
r-probfda	1.0.1	Probabilistic Fisher discriminant analysis (pFDA) is a probabilistic version of the popular and powerful Fisher linear discriminant analysis for dimensionality reduction and classification. / GPL-2	noarch
r-probhat	0.1.1	Computes nonparametric probability distributions (probability density functions, cumulative distribution functions and quantile functions) using kernel smoothing. Supports univariate, multivariate and conditional distributions, and weighted data (possibly useful mixed with fuzzy clustering or frequency data). Also, supports empirical continuous cumulative distribution functions and their inverses, and random number generation. / GPL-2	noarch
r-probsvm	1.00	This package provides multiclass conditional probability estimation for the SVM, which is distributional assumption free. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-proc	1.14.0	Tools for visualizing, smoothing and comparing receiver operating characteristic (ROC curves). (Partial) area under the curve (AUC) can be compared with statistical tests based on U-statistics or bootstrap. Confidence intervals can be computed for (p)AUC or ROC curves. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
r-proccalibrad	0.14	Package for processing downloaded MODIS Calibrated radiances Product HDF files. Specifically, MOD02 calibrated radiance product files, and the associated MOD03 geolocation files (for MODIS-TERRA). The package will be most effective if the user installs MRTSwath (MODIS Reprojection Tool for swath products; < https://lpdaac.usgs.gov/tools/modis_reprojection_tool_swath >, and adds the directory with the MRTSwath executable to the default R PATH by editing ~/.Rprofile. / GPL-2	noarch
r-processcontrol	0.1.0	Generate time series chart for individual values with mean and +/- 3 standard deviation lines and the corresponding mR chart with the upper control limit. Also execute the 8 Shewhart stability run tests and display the violations. / MIT	noarch
r-processx	3.3.0	Portable tools to run system processes in the background. It can check if a background process is running; wait on a background process to finish; get the exit status of finished processes; kill background processes and their children; restart processes. It can read the standard output and error of the processes, using non-blocking connections. 'processx' can poll a process for standard output or error, with a timeout. It can also poll several processes at once. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-prodigenr	0.5.0	Create a project directory structure, along with typical files for that project. This allows projects to be quickly and easily created, as well as for them to be standardized. Designed specifically with scientists in mind (mainly biomedical researchers, but likely applies to other fields). / MIT	noarch
r-prodlim	2018.04.18	Fast and user friendly implementation of nonparametric estimators for censored event history (survival) analysis. Kaplan-Meier and Aalen-Johansen method. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-profdpm	3.3	This package facilitates profile inference (inference at the posterior mode) for a class of product partition models (PPM). The Dirichlet process mixture is currently the only available member of this class. These methods search for the maximum posterior (MAP) estimate for the data partition in a PPM. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-profilelikelihood	1.1	This package provides profile likelihoods for a parameter of interest in commonly used statistical models. The models include linear models, generalized linear models, proportional odds models, linear mixed-effects models, and linear models for longitudinal responses fitted by generalized least squares. The package also provides plots for normalized profile likelihoods as well as the maximum profile likelihood estimates and the kth likelihood support intervals. / GPL-3	noarch
r-profilemodel	0.6.0	Provides tools that can be used to calculate, evaluate, plot and use for inference the profiles of <i>arbitrary</i> inference functions for <i>arbitrary</i> ‘glm’-like fitted models with linear predictors. More information on the methods that are implemented can be found in Kosmidis (2008) < https://www.r-project.org/doc/Rnews/Rnews_2008-2.pdf >. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-profmem	0.5.0	A simple and light-weight API for memory profiling of R expressions. The profiling is built on top of R’s built-in memory profiler (‘utils::Rprofmem()’), which records every memory allocation done by R (also native code). / LGPL-2.1	noarch
r-profr	0.3.3	An alternative data structure and visual rendering for the profiling information generated by Rprof. / MIT	noarch
r-proftools	0.99	Tools for examining Rprof profile output. / GPL-3	noarch
r-profvis	0.3.5	Interactive visualizations for profiling R code. / GPL-3 file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-prognosticroc	0.7	Prognostic ROC curve is an alternative graphical approach to represent the discriminative capacity of the marker: a receiver operating characteristic (ROC) curve by plotting 1 minus the survival in the high-risk group against 1 minus the survival in the low-risk group. This package contains functions to assess prognostic ROC curve. The user can enter the survival according to a model previously estimated or the user can also enter individual survival data for estimating the prognostic ROC curve by using Kaplan-Meier estimator. The area under the curve (AUC) corresponds to the probability that a patient in the low-risk group has a longer lifetime than a patient in the high-risk group. The prognostic ROC curve provides complementary information compared to survival curves. The AUC is assessed by using the trapezoidal rules. When survival curves do not reach 0, the prognostic ROC curve is incomplete and the extrapolations of the AUC are performed by assuming pessimist, optimist and non-informative situations. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-progress	1.2.0	Configurable Progress bars, they may include percentage, elapsed time, and/or the estimated completion time. They work in terminals, in ‘Emacs’ ‘ESS’, ‘RStudio’, ‘Windows’ ‘Rgui’ and the ‘macOS’ ‘R.app’. The package also provides a ‘C’ ‘API’, that works with or without ‘Rcpp’. / MIT file LICENSE	noarch
r-proj4	1.0_8	A simple interface to lat/long projection and datum transformation of the PROJ.4 cartographic projections library. It allows transformation of geographic coordinates from one projection and/or datum to another. / GPL-2	linux-64, osx-64
r-projecttemplate	0.9.0	Provides functions to automatically build a directory structure for a new R project. Using this structure, ‘ProjectTemplate’ automates data loading, pre-processing, library importing and unit testing. / GPL-3	noarch
r-projmgr	0.1.0	Provides programmatic access to ‘GitHub’ API with a focus on project management. Key functionality includes setting up issues and milestones from R objects or ‘YAML’ configurations, querying outstanding or completed tasks, and generating progress updates in tables, charts, and RMarkdown reports. Useful for those using ‘GitHub’ in personal, professional, or academic settings with an emphasis on streamlining the workflow of data analysis projects. / MIT	noarch
r-proliferativeindex	1.0.1	Provides functions for calculating and analyzing the proliferative index (PI) from an RNA-seq dataset. As described in Ramaker & Lasseigne, et al. bioRxiv, 2016 <doi:10.1101/063057>. / MIT	noarch
r-promethee	1.1	Functions which can be used to support the Multicriteria Decision Analysis (MCDA) process involving multiple criteria, by PROMETHEE (Preference Ranking Organization METHod for Enrichment of Evaluations). / GPL-3	noarch
r-promises	1.0.1	Provides fundamental abstractions for doing asynchronous programming in R using promises. Asynchronous programming is useful for allowing a single R process to orchestrate multiple tasks in the background while also attending to something else. Semantics are similar to ‘JavaScript’ promises, but with a syntax that is idiomatic R. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-promote	1.1.1	Deploy, maintain, and invoke predictive models using the ‘Alteryx Promote’ REST API. ‘Alteryx Promote’ is available at the URL: < https://www.alteryx.com/products/alteryx-promote >. / FreeBSD	noarch
r-propcis	0.3_0	Computes two-sample confidence intervals for single, paired and independent proportions. / GPL-3	noarch
r-properties	0.0_9	Allows to parse ‘Java’ properties files in the context of ‘R Service Bus’ applications. / GPL-2	noarch
r-propscrand	1.1	This package contains functions to run propensity-biased allocation to balance covariate distributions in sequential trials and propensity-constrained randomization to balance covariate distributions in trials with known baseline covariates at time of randomization. Currently this package only supports trials comparing two groups. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-proscorer tools	0.0.1	Provides a reliable and flexible toolbox to score patient-reported outcome (PRO), Quality of Life (QOL), and other psychometric measures. The guiding philosophy is that scoring errors can be eliminated by using a limited number of well-tested, well-behaved functions to score PRO-like measures. The workhorse of the package is the ‘scoreScale’ function, which can be used to score most single-scale measures. It can reverse code items that need to be reversed before scoring and pro-rate scores for missing item data. Currently, three different types of scores can be output: summed item scores, mean item scores, and scores scaled to range from 0 to 100. The ‘PROscorerTools’ functions can be used to write new functions that score more complex measures. In fact, ‘PROscorerTools’ functions are the building blocks of the scoring functions in the ‘PROscorer’ package (which is a repository of functions that score specific commonly-used instruments). Users are encouraged to use ‘PROscorerTools’ to write scoring functions for their favorite PRO-like instruments, and to submit these functions for inclusion in ‘PROscorer’ (a tutorial vignette will be added soon). The long-term vision for the ‘PROscorerTools’ and ‘PROscorer’ packages is to provide an easy-to-use system to facilitate the incorporation of PRO measures into research studies in a scientifically rigorous and reproducible manner. These packages and their vignettes are intended to help establish and promote best practices for scoring and describing PRO-like measures in research. / MIT	noarch
r-prospectr	0.1.3	The package provides functions for pretreatment and sample selection of visible and near infrared diffuse reflectance spectra / GPL-3	linux-64, osx-64, win-64
r-prosper	0.3.0	An environment to simulate the development of annual plant populations with regard to population dynamics and genetics, especially herbicide resistance. It combines genetics on the individual level (Renton et al. 2011) with a stochastic development on the population level (Daedlow, 2015). Renton, M, Diggle, A, Manalil, S and Powles, S (2011) <doi:10.1016/j.jtbi.2011.05.010> Daedlow, Daniel (2015, doctoral dissertation: University of Rostock, Faculty of Agriculture and Environmental Sciences.) / GPL-3	noarch
r-proteindescriptors	0.1.0	An implementation of protein descriptors in R. These descriptors combine the advantages of being fixed length and including partial sequential effect: Various length of protein sequences are described with fixed length vectors that are suitable for machine learning algorithms, and still includes partial sequential effect. / BSD_3_clause	noarch
r-proteomicdesign	2.0	This package provides functions to identify the optimal solution that maximizes numbers of detectable differentiated proteins from a multi-stage clinical proteomic study. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-proto	1.0.0	An object oriented system using object-based, also called prototype-based, rather than class-based object oriented ideas. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-protoclass	1.0	Greedy algorithm described in Bien and Tibshirani (2011) Prototype Selection for Interpretable Classification. Annals of Applied Statistics. 5(4). 2403-2424 / GPL-3	noarch
r-protoclust	1.6.3	Performs minimax linkage hierarchical clustering. Every cluster has an associated prototype element that represents that cluster as described in Bien, J., and Tibshirani, R. (2011), Hierarchical Clustering with Prototypes via Minimax Linkage, The Journal of the American Statistical Association, 106(495), 1075-1084. / GPL-2	linux-64, osx-64, win-64
r-protolidar	0.1	PROTOLIDAR package contains functions for analyze the LIDAR scan of plants (grapevine) and make 3D maps in GRASS GIS. / GPL-3	noarch
r-protolite	1.9	Optimized C implementations for reading and writing protocol-buffers. Currently supports 'rexp.proto' for serializing R objects and 'geobuf.proto' for geojson data. This lightweight package is complementary to the much larger 'RProtoBuf' package which provides a full featured toolkit for working with protocol-buffers in R. / MIT	linux-64, osx-64, win-64
r-proton	1.0	'The Proton Game' is a console-based data-crunching game for younger and older data scientists. Act as a data-hacker and find Slawomir Pietraszko's credentials to the Proton server. You have to solve four data-based puzzles to find the login and password. There are many ways to solve these puzzles. You may use loops, data filtering, ordering, aggregation or other tools. Only basics knowledge of R is required to play the game, yet the more functions you know, the more approaches you can try. The knowledge of dplyr is not required but may be very helpful. This game is linked with the „Pietraszko's Cave" story available at http://biecek.pl/BetaBit/Warsaw . It's a part of Beta and Bit series. You will find more about the Beta and Bit series at http://biecek.pl/BetaBit . / GPL-2	noarch
r-protr	1.6_2	Comprehensive toolkit for generating various numerical features of protein sequences described in Xiao et al. (2015) <DOI:10.1093/bioinformatics/btv042>. For full functionality, the software 'ncbi-blast' is needed, see < https://blast.ncbi.nlm.nih.gov/Blast.cgi?PAGE_TYPE=BlastDocs&DOC_TYPE=Download > for more information. / BSD_3_clause	noarch
r-protviz	0.4.0	Helps with quality checks, visualizations and analysis of mass spectrometry data, coming from proteomics experiments. The package is developed, tested and used at the Functional Genomics Center Zurich. We use this package mainly for prototyping, teaching, and having fun with proteomics data. But it can also be used to do data analysis for small scale data sets. / GPL-3	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-provparser	0.2	R functions to access provenance information collected by ‘rdt’ or ‘rdtLite’. The information is stored inside a ‘ProvInfo’ object and can be accessed through a collection of functions that will return the requested data. The exact format of the JSON created by ‘rdt’ and ‘rdtLite’ is described in < https://github.com/End-to-end-provenance/ExtendedProvJson >. / GPL-3	noarch
r-provviz	1.0.6	Displays provenance graphically for provenance collected by the ‘rdt’ or ‘rdtLite’ packages, or other tools providing compatible PROV JSON output. The exact format of the JSON created by ‘rdt’ and ‘rdtLite’ is described in < https://github.com/End-to-end-provenance/ExtendedProvJson >. More information about rdtLite and associated tools is available at < https://github.com/End-to-end-provenance/ > and Barbara Lerner, Emery Boose, and Luis Perez (2018), Using Introspection to Collect Provenance in R, Informatics, <doi:10.3390/informatics5010012>. / GPL-3	noarch
r-proxy	0.4_2	Provides an extensible framework for the efficient calculation of auto- and cross-proximities, along with implementations of the most popular ones. / GPL-2	linux-64, osx-64, win-64
r-prroc	1.3.1	Computes the areas under the precision-recall (PR) and ROC curve for weighted (e.g., soft-labeled) and unweighted data. In contrast to other implementations, the interpolation between points of the PR curve is done by a non-linear piecewise function. In addition to the areas under the curves, the curves themselves can also be computed and plotted by a specific S3-method. References: Davis and Goadrich (2006) <doi:10.1145/1143844.1143874>; Keilwagen et al. (2014) <doi:10.1371/journal.pone.0092209>; Grau et al. (2015) <doi:10.1093/bioinformatics/btv153>. / GPL-3	noarch
r-prsr	3.1.1_2	Tests periodicity in short time series using response surface regression. / GPL-2	linux-64, osx-64, win-64
r-pryr	0.1.4	Useful tools to pry back the covers of R and understand the language at a deeper level. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-ps	1.3.0	List, query and manipulate all system processes, on ‘Windows’, ‘Linux’ and ‘macOS’. / BSD_3_clause file LICENSE	linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-psagraphics	2.1.1	A collection of functions that primarily produce graphics to aid in a Propensity Score Analysis (PSA). Functions include: cat.psa and box.psa to test balance within strata of categorical and quantitative covariates, circ.psa for a representation of the estimated effect size by stratum, loess.psa that provides a graphic and loess based effect size estimate, and various balance functions that provide measures of the balance achieved via a PSA in a categorical covariate. / GPL-2	noarch
r-pscl	1.5.2	Bayesian analysis of item-response theory (IRT) models, roll call analysis; computing highest density regions; maximum likelihood estimation of zero-inflated and hurdle models for count data; goodness-of-fit measures for GLMs; data sets used in writing and teaching at the Political Science Computational Laboratory; seats-votes curves. / GPL-2	linux-64, osx-64, win-64
r-pseval	1.3.1	Contains the core methods for the evaluation of principal surrogates in a single clinical trial. Provides a flexible interface for defining models for the risk given treatment and the surrogate, the models for integration over the missing counterfactual surrogate responses, and the estimation methods. Estimated maximum likelihood and pseudo-score can be used for estimation, and the bootstrap for inference. A variety of post-estimation summary methods are provided, including print, summary, plot, and testing. / MIT	noarch
r-psi	1.1	This package contains functions to calculate the Specificity Index statistic, which can be used for comparative quantitative analysis to identify genes enriched in specific cell populations across a large number of profiles, as well as perform numerous post-processing operations. NOTE:Supplementary data (human & mouse expression sets, calculated pSI datasets, etc.) can be found in pSI.data package located at the following URL: http://genetics.wustl.edu/jdlab/psi_package/ / GPL-2	noarch
r-psy	1.0.3	The package provides an implementation of PSO consistent with the standard PSO 2007/2011 by Maurice Clerc et al. Additionally a number of ancillary routines are provided for easy testing and graphics. / LGPL-3	noarch
r-psoptim	1.0	Particle swarm optimization - a basic variant. / GPL (>= 2.0)	noarch
r-pspearman	0.3_0	Spearman's rank correlation test with precomputed exact null distribution for n <= 22. / GPL-3	linux-64, osx-64, win-64
r-pspline	1.0_1	Smoothing splines with penalties on order m derivatives. / Unlimited	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pstat	1.2	Calculating Pst values to assess differentiation among populations from a set of quantitative traits is the primary purpose of such a package. The bootstrap method provides confidence intervals and distribution histograms of Pst. Variations of Pst in function of the parameter c/h^2 are studied as well. Finally, the package proposes different transformations especially to eliminate any variation resulting from allometric growth (calculation of residuals from linear regressions, Reist standardizations or Aitchison transformation). / GPL-2	noarch
r-psumtsim	0.4	Functions to simulate Poisson or Normally distributed responses relative to a baseline and compute achieved significance level and powers for tests on the simulated responses. / GPL-3	noarch
r-psy	1.1	Kappa, ICC, Cronbach alpha, screeplot, mtmm / GPL-2	noarch
r-psych	1.8.1	A general purpose toolbox for personality, psychometric theory and experimental psychology. Functions are primarily for multivariate analysis and scale construction using factor analysis, principal component analysis, cluster analysis and reliability analysis, although others provide basic descriptive statistics. Item Response Theory is done using factor analysis of tetrachoric and polychoric correlations. Functions for analyzing data at multiple levels include within and between group statistics, including correlations and factor analysis. Functions for simulating and testing particular item and test structures are included. Several functions serve as a useful front end for structural equation modeling. Graphical displays of path diagrams, factor analysis and structural equation models are created using basic graphics. Some of the functions are written to support a book on psychometric theory as well as publications in personality research. For more information, see the < https://personality-project.org/r/ > web page. / GPL (≥ 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-psychotools	0.5.0	Infrastructure for psychometric modeling such as data classes (for item response data and paired comparisons), basic model fitting functions (for Bradley-Terry, Rasch, parametric logistic IRT, generalized partial credit, rating scale, multinomial processing tree models), extractor functions for different types of parameters (item, person, threshold, discrimination, guessing, upper asymptotes), unified inference and visualizations, and various datasets for illustration. Intended as a common lightweight and efficient toolbox for psychometric modeling and a common building block for fitting psychometric mixture models in package psychomix and trees based on psychometric models in package psychotree. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-psychtools	1.9.5	Support functions, data sets, and vignettes for the ‘psych’ package. Contains several of the biggest data sets for the ‘psych’ package as well as one vignette. A few helper functions for file manipulation are included as well. For more information, see the < https://personality-project.org/r/ > web page. / GPL-2	noarch
r-psymonitor	0.0.2	Apply the popular real-time monitoring strategy proposed by Phillips, Shi and Yu (2015a,b;PSY) <doi:10.1111/iere.12132>, <doi:10.1111/iere.12131>, along with a new bootstrap procedure designed to mitigate the potential impact of heteroskedasticity and to effect family-wise size control in recursive testing algorithms (Phillips and Shi, forthcoming). / GPL-3	noarch
r-psyphy	0.1.9	An assortment of functions that could be useful in analyzing data from psychophysical experiments. It includes functions for calculating d' from several different experimental designs, links for m-alternative forced-choice (mafc) data to be used with the binomial family in glm (and possibly other contexts) and self-Start functions for estimating gamma values for CRT screen calibrations. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pte	1.7	We provide inference for personalized medicine models. Namely, we answer the questions: (1) how much better does a purported personalized recommendation engine for treatments do over a business-as-usual approach and (2) is that difference statistically significant? / GPL-3	noarch
r-ptest	1.0.8	Implements p-value computations using an approximation to the cumulative distribution function for a variety of tests for periodicity. These tests include harmonic regression tests with normal and double exponential errors as well as modifications of Fisher's g test. An accompanying vignette illustrates the application of these tests. / GPL-2	linux-64, osx-64, win-64
r-ptprocess	3.3.1	Fits and analyses time dependent marked point process models with an emphasis on earthquake modelling. For a more detailed introduction to the package, see the topic PtProcess. A list of recent changes can be found in the topic Change Log. / GPL-2	noarch
r-pts2polys	0.1.1	Various applications in invasive species biology, conservation biology, epidemiology and elsewhere involve sampling of sets of 2D points from a posterior distribution. The number of such point sets may be large, say 1000 or 10000. This package facilitates visualisation of such output by constructing seven nested polygons representing the location and variability of the point sets. This can be used, for example, to visualise the range boundary of a species, and uncertainty in the location of that boundary. / GPL-2	linux-64, osx-64, win-64
r-ptsuite	1.0.0	Various estimation methods for the shape parameter of Pareto distributed data. This package contains functions for various estimation methods such as maximum likelihood (Newman, 2005)<doi:10.1016/j.cities.2012.03.001>, Hill's estimator (Hill, 1975)<doi:10.1214/aos/1176343247>, least squares (Zaher et al., 2014)<doi:10.9734/BJMCS/2014/10890>, method of moments (Rytgaard, 1990)<doi:10.2143/AST.20.2.2005443>, percentiles (Bhatti et al., 2018)<doi:10.1371/journal.pone.0196456>, and weighted least squares (Nair et al., 2019) to estimate the shape parameter of Pareto distributed data. It also provides both a heuristic method (Hubert et al., 2013)<doi:10.1016/j.csda.2012.07.011> and a goodness of fit test (Gulati and Shapiro, 2008)<doi:10.1007/978-0-8176-4619-6> for testing for Pareto data as well as a method for generating Pareto distributed data. / GPL-3	linux-64, osx-64, win-64
r-ptw	1.9.1	Parametric Time Warping aligns patterns, i.e. it aims to put corresponding features at the same locations. The algorithm searches for an optimal polynomial describing the warping. It is possible to align one sample to a reference, several samples to the same reference, or several samples to several references. One can choose between calculating individual warpings, or one global warping for a set of samples and one reference. Two optimization criteria are implemented: RMS (Root Mean Square error) and WCC (Weighted Cross Correlation). Both warping of peak profiles and of peak lists are supported. / GPL-2	linux-64, osx-64, win-64
r-ptwikiwords	0.0.3	Contains a dataset of words used in 15,000 randomly extracted pages from the Portuguese Wikipedia (< https://pt.wikipedia.org/ >). / MIT	noarch
r-ptycho	1.1.4	Bayesian variable selection for linear regression models using hierarchical priors. There is a prior that combines information across responses and one that combines information across covariates, as well as a standard spike and slab prior for comparison. An MCMC samples from the marginal posterior distribution for the 0-1 variables indicating if each covariate belongs to the model for each response. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-publish	2018.04.17	Convenience functions that transform the results of some basic statistical analyses into table format nearly ready for publication. This includes descriptive tables, tables of logistic regression and Cox regression results as well as forest plots. / GPL-2	noarch
r-pullword	0.2	R Interface to Pullword Service for natural language processing in Chinese. It enables users to extract valuable words from text by deep learning models. For more details please visit the official site (in Chinese) http://pullword.com/ . / LGPL-3	linux-64, osx-64, win-64
r-pulsar	0.3.6	Model selection for penalized graphical models using the Stability Approach to Regularization Selection ('StARS'), with options for speed-ups including Bounded StARS (B-StARS), batch computing, and other stability metrics (e.g., graphlet stability G-StARS). Christian L. Müller, Richard Bonneau, Zachary Kurtz (2016) <arXiv:1605.07072>. / GPL-2	noarch
r-pumilior	1.3.1	R package to query and get data out of a Pumilio sound archive system (http://ljvillanueva.github.io/pumilio/). / GPL-3	noarch
r-purge	0.2.1	Enables the removal of training data from fitted R models while retaining predict functionality. The purged models are more portable as their memory footprints do not scale with the training sample size. / MIT	noarch
r-purging	1.0.0	Simple method of purging independent variables of mediating effects. First, regress the direct variable on the indirect variable. Then, used the stored residuals as the new purged (direct) variable in the updated specification. This purging process allows for use of a new direct variable uncorrelated with the indirect variable. Please cite the method and/or package using Waggoner, Philip D. (2018) <doi:10.1177/1532673X18759644>. / MIT	noarch
r-purrr	0.3.2	A complete and consistent functional programming toolkit for R. / GPL-3 file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-pushbar	0.1.0	Create sliders from left, right, top and bottom which may include any html or 'Shiny' input or output. / MIT	noarch
r-pushoverr	1.0.0	Send push notifications to mobile devices or the desktop using Pushover. These notifications can display job status, results, scraped web data, or any other text or numeric data. / BSD_2_clause	noarch
r-pvclass	1.4	Computes nonparametric p-values for the potential class memberships of new observations as well as cross-validated p-values for the training data. The p-values are based on permutation tests applied to an estimated Bayesian likelihood ratio, using a plug-in statistic for the Gaussian model, 'k nearest neighbors', 'weighted nearest neighbors' or 'penalized logistic regression'. Additionally, it provides graphical displays and quantitative analyses of the p-values. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-pvclust	2.0_0	An implementation of multiscale bootstrap resampling for assessing the uncertainty in hierarchical cluster analysis. It provides AU (approximately unbiased) p-value as well as BP (bootstrap probability) value for each cluster in a dendrogram. / GPL-2	noarch
r-pvsr	0.3	The pvsR package facilitates data retrieval from Project Vote Smart's rich on-line data base on US politics via the Project Vote Smart application programming interface (PVS API). The functions in this package cover most PVS API classes and methods and return the requested data in a data frame. / GPL-2	noarch
r-pwr	1.2_2	Power analysis functions along the lines of Cohen (1988). / GPL-3	noarch
r-pwr2	1.0	User friendly functions for power and sample size analysis at one-way and two-way ANOVA settings take either effect size or delta and sigma as arguments. They are designed for both one-way and two-way ANOVA settings. In addition, a function for plotting power curves is available for power comparison, which can be easily visualized by statisticians and clinical researchers. / GPL-2	noarch
r-pwrab	0.1.0	Power analysis for AB testing. The calculations are based on the Welch's unequal variances t-test, which is generally preferred over the Student's t-test when sample sizes and variances of the two groups are unequal, which is frequently the case in AB testing. In such situations, the Student's t-test will give biased results due to using the pooled standard deviation, unlike the Welch's t-test. / GPL-3	noarch
r-pwrrasch	0.1_2	Statistical power simulation for testing the Rasch Model based on a three-way analysis of variance design with mixed classification. / GPL-3	noarch
r-pwt	7.1_1	The Penn World Table provides purchasing power parity and national income accounts converted to international prices for 189 countries for some or all of the years 1950-2010. / GPL-2	noarch
r-pwt8	8.1_1	The Penn World Table 8.x provides information on relative levels of income, output, inputs, and productivity for 167 countries between 1950 and 2011. / GPL-2 GPL-3	noarch
r-pwt9	9.1_0	The Penn World Table 9.x (< http://www.ggd.net/pwt/ >) provides information on relative levels of income, output, inputs, and productivity for 182 countries between 1950 and 2017. / GPL-2 GPL-3	noarch
r-pxr	0.42	Provides a set of functions for reading and writing PC-Axis files, used by different statistical organizations around the globe for data dissemination. / GPL-3	noarch
r-pxweb	0.9.1	Generic interface for the PX-Web/PC-Axis API. The PX-Web/PC-Axis API is used by organizations such as Statistics Sweden and Statistics Finland to disseminate data. The R package can interact with all PX-Web/PC-Axis APIs to fetch information about the data hierarchy, extract metadata and extract and parse statistics to R data.frame format. PX-Web is a solution to disseminate PC-Axis data files in dynamic tables on the web. Since 2013 PX-Web contains an API to disseminate PC-Axis files. / BSD_2_clause	noarch
r-pymturkr	1.1	Provides access to the latest 'Amazon Mechanical Turk' ('MTurk') < https://www.mturk.com > Requester API (version '2017-01-17'), replacing the now deprecated 'MTurkR' package. / GPL-2	noarch
r-pyramid	1.5	Drawing population pyramid using (1) data.frame or (2) vectors. The former is named as pyramid() and the latter pyramids(), as wrapper function of pyramid(). pyramidf() is the function to draw population pyramid within the specified frame. / GPL-2	noarch
r-pzfx	0.2.0	Read and write 'GraphPad Prism' '.pzfx' files in R. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-qaig	0.1.5	A tool for automatic generation of sibling items from a parent item model defined by the user. It is an implementation of the process automatic item generation (AIG) focused on generating quantitative multiple-choice type of items (see Embretson, Kingston (2018) <doi:10.1111/jedm.12166>). / GPL-3	noarch
r-qboxplot	0.2	Produce quantile-based box-and-whisker plot(s). / GPL-2	noarch
r-qcafalsepositive	1.1.1	Implements tests for Type I error in Qualitative Comparative Analysis (QCA) that take into account the multiple hypothesis tests inherent in the procedure. Tests can be carried out on three variants of QCA: crisp-set QCA (csQCA), multi-value QCA (mvQCA) and fuzzy-set QCA (fsQCA). For fsQCA, the fsQCApermTest() command implements a permutation test that provides 95% confidence intervals for the number of counterexamples and degree of consistency, respectively. The distributions of permuted values can be plotted against the observed values. For csQCA and mvQCA, simple binomial tests are implemented in csQCAbinTest() and mvQCAbinTest(), respectively. / GPL-3	noarch
r-qcba	0.3.1	CBA postprocessing algorithm that creates smaller models for datasets containing quantitative (numerical) attributes. Article describing QCBA is published in Tomas Kliegr (2017) <arXiv:1711.10166>. / AGPL-3	noarch
r-qcc	2.7	Shewhart quality control charts for continuous, attribute and count data. Cusum and EWMA charts. Operating characteristic curves. Process capability analysis. Pareto chart and cause-and-effect chart. Multivariate control charts. / GPL-2	noarch
r-qcewas	1.2_2	Tools for (automated and manual) quality control of the results of Epigenome-Wide Association Studies. / GPL-3	noarch
r-qcgwas	1.0_8	Tools for (automated and manual) quality control of the results of Genome Wide Association Studies / GPL-3	noarch
r-qcsis	0.1	Quantile correlation-sure independence screening (QC-SIS) and composite quantile correlation-sure independence screening (CQC-SIS) for ultrahigh-dimensional data. / GPL-2	noarch
r-qcv	1.0	Primarily, the ‘qcv’ package computes key indices related to the Quantifying Construct Validity procedure (QCV; Westen & Rosenthal, 2003 <doi:10.1037/0022-3514.84.3.608>; see also Furr & Heuckeroth, in press). The qcv() function is the heart of the ‘qcv’ package, but additional functions in the package provide useful ancillary information related to the QCV procedure. / GPL-2	noarch
r-qdapdictionaries	1.0.7	A collection of text analysis dictionaries and word lists for use with the ‘qdap’ package. / GPL-2	noarch
r-qdapregex	0.7.2	A collection of regular expression tools associated with the ‘qdap’ package that may be useful outside of the context of discourse analysis. Tools include removal/extraction/replacement of abbreviations, dates, dollar amounts, email addresses, hash tags, numbers, percentages, citations, person tags, phone numbers, times, and zip codes. / GPL-2	noarch
r-qdaptools	1.3.3	A collection of tools associated with the ‘qdap’ package that may be useful outside of the context of text analysis. / GPL-2	noarch
r-qdcomparison	3.0	Allows practitioners to determine (i) if two univariate distributions (which can be continuous, discrete, or even mixed) are equal, (ii) how two distributions differ (shape differences, e.g., location, scale, etc.), and (iii) where two distributions differ (at which quantiles), all using nonparametric LP statistics. The primary reference is Jungreis, D. (2019, Technical Report). / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-qdm	0.1.0	This package provides different specifications of a Quadrilateral Dissimilarity Model which can be used to fit same-different judgments in order to get a predicted matrix that satisfies regular minimality [Colonius & Dzhafarov, 2006, Measurement and representations of sensations, Erlbaum]. From such a matrix, Fechnerian distances can be computed. / GPL-2	noarch
r-qfrm	1.0.1	Option pricing (financial derivatives) techniques mainly following textbook ‘Options, Futures and Other Derivatives’, 9ed by John C.Hull, 2014. Prentice Hall. Implementations are via binomial tree option model (BOPM), Black-Scholes model, Monte Carlo simulations, etc. This package is a result of Quantitative Financial Risk Management course (STAT 449 and STAT 649) at Rice University, Houston, TX, USA, taught by Oleg Melnikov, statistics PhD student, as of Spring 2015. / GPL-2	noarch
r-qgglmm	0.7.2	Compute various quantitative genetics parameters from a Generalised Linear Mixed Model (GLMM) estimates. Especially, it yields the observed phenotypic mean, phenotypic variance and additive genetic variance. / GPL-2	noarch
r-qgtools	1.0	Two linear mixed model approaches: REML(restricted maximum likelihood) and MINQUE (minimum norm quadratic unbiased estimation) approaches and several resampling techniques are integrated for various quantitative genetics analyses. With these two types of approaches, various unbalanced data structures, missing data, and any irregular genetic mating designs can be analyzed and statistically tested. This package also offers fast computations for many large data sets. Other functions will be added to this R tool in the future. / GPL-2	noarch
r-qhot	0.1.0	This function produces both the numerical and graphical summaries of the QTL hotspot detection in the genomes that are available on the worldwide web including the flanking markers of QTLs. / GPL-3	noarch
r-qiitr	0.1.0	Qiita is a technical knowledge sharing and collaboration platform for programmers. See < https://qiita.com/api/v2/docs > for more information. / MIT	noarch
r-qkerntool	1.19	Nonlinear machine learning tool for classification, clustering and dimensionality reduction. It integrates 12 q-kernel functions and 15 conditional negative definite kernel functions and includes the q-kernel and conditional negative definite kernel version of density-based spatial clustering of applications with noise, spectral clustering, generalized discriminant analysis, principal component analysis, multidimensional scaling, locally linear embedding, sammon’s mapping and t-Distributed stochastic neighbor embedding. / GPL-2	noarch
r-qlearn	1.0	Functions to implement Q-learning for estimating optimal dynamic treatment regimes from two stage sequentially randomized trials, and to perform inference via m-out-of-n bootstrap for parameters indexing the optimal regime. / GPL-2	noarch
r-qlearning	0.1.1	Implements Q-Learning, a model-free form of reinforcement learning, described in work by Strehl, Li, Wiewiora, Langford & Littman (2006) <doi:10.1145/1143844.1143955>. / GPL-3	noarch
r-qmrparser	0.1.5	Basic functions for building parsers, with an application to PC-AXIS format files. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-qpdf	1.1	Content-preserving transformations of PDF files such as split, combine, and compress. This package interfaces directly to the ‘qpdf’ C API and does not require any command line utilities. Note that ‘qpdf’ does not read actual content from PDF files: to extract text and data you need the ‘pdftools’ package. / Apache License 2.0	linux-64, osx-64, win-32, win-64
r-qqman	0.1.4	Create Q-Q and manhattan plots for GWAS data from PLINK results. / GPL-3	noarch
r-qqperm	1.0.1	Provides users the necessary utility functions to generate permutation-based QQ plots and also estimate inflation factor based on the empirical NULL distribution. While it has general utility, it is particularly helpful when the skewness of the Fisher’s Exact test in sparse data situations with imbalanced case-control sample sizes renders the reliance on the uniform chi-square expected distribution inappropriate. / GPL-2	noarch
r-qqvases	1.0.0	Presents an explanatory animation of normal quantile-quantile plots based on a water-filling analogy. The animation presents a normal QQ plot as the parametric plot of the water levels in vases defined by two distributions. The distributions decorate the axes in the normal QQ plot and are optionally shown as vases adjacent to the plot. The package draws QQ plots for several distributions, either as samples or continuous functions. / GPL-2	noarch
r-qrage	1.0	Tools that create D3 JavaScript force directed graph from R. D3 JavaScript was created by Michael Bostock. See http://d3js.org/ and, more specifically for Force Directed Graph https://github.com/mbostock/d3/wiki/Force-Layout . / MIT	noarch
r-qrank	1.0	A Quantile Rank-score based test for the identification of expression quantitative trait loci. / GPL-2	noarch
r-qrcode	0.1.1	Create QRcode in R. / GPL-3	noarch
r-qrm	0.4.1	Accompanying package to the book Quantitative Risk Management: Concepts, Techniques and Tools by Alexander J. McNeil, Rüdiger Frey, and Paul Embrechts. / GPL (>= 2)	linux-64, osx-64, win-32, win-64
r-qrmdata	2016.01.03	Various data sets (stocks, stock indices, constituent data, FX, zero-coupon bond yield curves, volatility, commodities) for Quantitative Risk Management practice. / GPL-2 GPL-3	noarch
r-qrmix	0.9.0	Implements the robust algorithm for fitting finite mixture models based on quantile regression proposed by Emir et al., 2017 (unpublished). / LGPL-3	noarch
r-qrnn	2.0.4	Fit quantile regression neural network models with optional left censoring, partial monotonicity constraints, generalized additive model constraints, and the ability to fit multiple non-crossing quantile functions following Cannon (2011) <doi:10.1016/j.cageo.2010.07.005> and Cannon (2018) <doi:10.1007/s00477-018-1573-6>. / GPL-2	noarch

Name	Version	Summary/License	Platforms
r-qrsvm	0.2.1	Quantile Regression (QR) using Support Vector Machines under the Pinball-Loss. Estimation is based on Nonparametric Quantile Regression by I. Takeuchi, Q.V.Le , T. Sears, A.J.Smola (2004). Implementation relies on ‘quadprog’ package, package ‘kernlab’ Kernelfunctions and package ‘Matrix’ nearPD to find next Positive definite Kernelmatrix. Package estimates quantiles individually but an Implementation of non crossing constraints coming soon. Function multqrsvm() now supports parallel backend for faster fitting. / GPL-2	noarch
r-qsardata	1.3	Molecular descriptors and outcomes for several public domain data sets / GPL-3	noarch
r-qtlbook	0.18	Datasets for the book, A Guide to QTL Mapping with R/qtl. Broman and Sen (2009) <doi:10.1007/978-0-387-92125-9>. / GPL-3	noarch
r-qtlDesign	0.94	Tools for the design of QTL experiments / GPL-3	noarch
r-quadprog	1.5_5	This package contains routines and documentation for solving quadratic programming problems. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-quadprogxt	0.0.4	Extends the quadprog package to solve quadratic programs with absolute value constraints and absolute values in the objective function. / GPL-2	noarch
r-qualci	0.1	Exact one-sided p-values and confidence intervals for an outcome variable defined on an interval measurement scale with only qualitative and ordinal information available. / GPL-2	noarch
r-qualvar	0.2.0	Implements indices of qualitative variation proposed by Wilcox (1973). / GPL-3	noarch
r-quandl	2.10.0	Functions for interacting directly with the Quandl API to offer data in a number of formats usable in R, downloading a zip with all data from a Quandl database, and the ability to search. This R package uses the Quandl API. For more information go to < https://www.quandl.com/docs/api >. For more help on the package itself go to < https://www.quandl.com/help/r >. / MIT	noarch
r-quantileda	1.1	Code for centroid, median and quantile classifiers. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-quantilegrader	0.1.1	Implementation of the food safety restaurant grading system adopted by Public Health - Seattle & King County (see Ashwood, Z.C., Elias, B., and Ho. D.E. Improving the Reliability of Food Safety Disclosure: A Quantile Adjusted Restaurant Grading System for Seattle-King County (working paper)). As reported in the accompanying paper, this package allows jurisdictions to easily implement refinements that address common challenges with unadjusted grading systems. First, in contrast to unadjusted grading, where the most recent single routine inspection is the primary determinant of a grade, grading inputs are allowed to be flexible. For instance, it is straightforward to base the grade on average inspection scores across multiple inspection cycles. Second, the package can identify quantile cutoffs by inputting substantively meaningful regulatory thresholds (e.g., the proportion of establishments receiving sufficient violation points to warrant a return visit). Third, the quantile adjustment equalizes the proportion of establishments in a flexible number of grading categories (e.g., A/B/C) across areas (e.g., ZIP codes, inspector areas) to account for inspector differences. Fourth, the package implements a refined quantile adjustment that addresses two limitations with the stats::quantile() function when applied to inspection score datasets with large numbers of score ties. The quantile adjustment algorithm iterates over quantiles until, over all restaurants in all areas, grading proportions are within a tolerance of desired global proportions. In addition the package allows a modified definition of quantile from Nearest Rank. Instead of requiring that at least $p[1]\%$ of restaurants receive the top grade and at least $(p[1]p[2])\%$ of restaurants receive the top or second best grade for quantiles p , the algorithm searches for cutoffs so that as close as possible $p[1]\%$ of restaurants receive the top grade, and as close as possible to $p[2]\%$ of restaurants receive the second top grade. / GPL-2	noarch
r-quantilenpci	0.9.0	Based on Alan D. Hutson (1999) <doi:10.1080/02664769922458>, Calculating nonparametric confidence intervals for quantiles using fractional order statistics, Journal of Applied Statistics, 26:3, 343-353. / GPL-3	noarch
r-quantmod	0.4.1	Specify, build, trade, and analyse quantitative financial trading strategies. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-quantnorm	1.0.5	Modifies the distance matrix obtained from data with batch effects, so as to improve the performance of sample pattern detection, such as clustering, dimension reduction, and construction of networks between subjects. The method has been published in Bioinformatics (Fei et al, 2018, <doi:10.1093/bioinformatics/bty117>). Also available on 'GitHub' <https://github.com/tengfei-emory/QuantNorm>. / GPL-2	noarch
r-quantpsyc	1.5	Contains functions useful for data screening, testing moderation, mediation and estimating power. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-quantreg	5.38	Estimation and inference methods for models of conditional quantiles: Linear and nonlinear parametric and non-parametric (total variation penalized) models for conditional quantiles of a univariate response and several methods for handling censored survival data. Portfolio selection methods based on expected shortfall risk are also included. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-quantreggrowth	0.4_3	Fits non-crossing regression quantiles as a function of linear covariates and multiple smooth terms via B-splines with L1-norm difference penalties. Monotonicity constraints on the fitted curves are allowed. See Muggeo, Sciandra, Tomasello and Calvo (2013) <doi:10.1007/s10651-012-0232-1> and <doi:10.13140/RG.2.2.12924.85122> for some code example. / GPL-3	noarch
r-quantumops	2.5.3	Contains basic structures and operations used frequently in quantum computing. Intended to be a convenient tool to help learn quantum mechanics and algorithms. Can create arbitrarily sized kets and bras and implements quantum gates, inner products, and tensor products. Creates arbitrarily controlled versions of all gates and can simulate complete or partial measurements of kets. Has functionality to convert functions into equivalent quantum gates. Includes larger applications, such as Steane error correction <DOI:10.1103/physrevlett.77.793>, Quantum Fourier Transform and Shor's algorithm (Shor 1999), Grover's algorithm (1996), Quantum Approximation Optimization Algorithm (QAOA) (Farhi, Goldstone, and Gutmann 2014) <arXiv:1411.4028>, and a variational quantum classifier (Schuld 2018) <arXiv:1804.00633>. / GPL-3	noarch
r-quclu	0.1.0	Various quantile-based clustering algorithms: algorithm CU (Common theta and Unscaled variables), algorithm CS (Common theta and Scaled variables through lambda_j), algorithm VU (Variable-wise theta_j and Unscaled variables) and algorithm VW (Variable-wise theta_j and Scaled variables through lambda_j). Hennig, Viroli, Anderlucci (2018) <arXiv:1806.10403v1>. / GPL-2 GPL-3	noarch
r-queryparser	0.1.1	Translate 'SQL' 'SELECT' statements into lists of 'R' expressions. / Apache License 2.0	noarch
r-queueing	0.2.1	It provides versatile tools for analysis of birth and death based Markovian Queueing Models and Single and Multiclass Product-Form Queueing Networks. It implements M/M/1, M/M/c, M/M/Infinite, M/M/1/K, M/M/c/K, M/M/c/c, M/M/1/K/K, M/M/c/K/K, M/M/c/K/m, M/M/Infinite/K/K, Multiple Channel Open Jackson Networks, Multiple Channel Closed Jackson Networks, Single Channel Multiple Class Open Networks, Single Channel Multiple Class Closed Networks and Single Channel Multiple Class Mixed Networks. Also it provides a B-Erlang, C-Erlang and Engset calculators. This work is dedicated to the memory of D. Sixto Rios Insua. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-quiddich	1.0.0	Provides tools for an automated identification of diagnostic molecular characters, i.e. such columns in a given nucleotide or amino acid alignment that allow to distinguish taxa from each other. These characters can then be used to complement the formal descriptions of the taxa, which are often based on morphological and anatomical features. Especially for morphologically cryptic species, this will be helpful. QUIDDICH distinguishes between four different types of diagnostic characters. For more information, see Kuehn, A.L., Haase, M. 2019. QUIDDICH: QUick IDentification of DIagnostic CHaracters. / GPL-3	noarch
r-quietr	0.1.0	Simplifies output suppression logic in R packages, as it's common to develop some form of it in R. 'quietR' intends to simplify that problem and allow a set of simple toggle functions to be used to suppress console output. / MIT	noarch
r-quran	0.1.0	Full text, in data frames containing one row per verse, of the Qur'an in Arabic (with and without vowels) and in English (the Yusuf Ali and Saheeh International translations), formatted to be convenient for text analysis. / MIT	noarch
r-qvcalc	0.9.1	Functions to compute quasi variances and associated measures of approximation error. / GPL-2 GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-r.blip	1.1	Allows the user to learn Bayesian networks from datasets containing thousands of variables. It focuses on score-based learning, mainly the 'BIC' and the 'BDeu' score functions. It provides state-of-the-art algorithms for the following tasks: (1) parent set identification - Mauro Scanagatta (2015) < http://papers.nips.cc/paper/5803-learning-bayesian-networks-with-thousands-of-variables >; (2) general structure optimization - Mauro Scanagatta (2018) <doi:10.1007/s10994-018-5701-9>, Mauro Scanagatta (2018) < http://proceedings.mlr.press/v73/scanagatta17a.html >; (3) bounded treewidth structure optimization - Mauro Scanagatta (2016) < http://papers.nips.cc/paper/6232-learning-treewidth-bounded-bayesian-networks-with-thousands-of-variables >; (4) structure learning on incomplete data sets - Mauro Scanagatta (2018) <doi:10.1016/j.ijar.2018.02.004>. Distributed under the LGPL-3 by IDSIA. / LGPL-3	noarch
r-r.cache	0.13.0	Memoization can be used to speed up repetitive and computational expensive function calls. The first time a function that implements memoization is called the results are stored in a cache memory. The next time the function is called with the same set of parameters, the results are momentarily retrieved from the cache avoiding repeating the calculations. With this package, any R object can be cached in a key-value storage where the key can be an arbitrary set of R objects. The cache memory is persistent (on the file system). / LGPL-2.1	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-r.devices	2.16.0	Functions for creating plots and image files in a unified way regardless of output format (EPS, PDF, PNG, SVG, TIFF, WMF, etc.). Default device options as well as scales and aspect ratios are controlled in a uniform way across all device types. Switching output format requires minimal changes in code. This package is ideal for large-scale batch processing, because it will never leave open graphics devices or incomplete image files behind, even on errors or user interrupts. / LGPL-2.1	noarch
r-r.huge	0.9.0	DEPRECATED. Do not start building new projects based on this package. Cross-platform alternatives are the following packages: bigmemory (CRAN), ff (CRAN), BufferedMatrix (Bioconductor). The main usage of it was inside the aroma.affymetrix package. (The package currently provides a class representing a matrix where the actual data is stored in a binary format on the local file system. This way the size limit of the data is set by the file system and not the memory.) / LGPL-2.1	noarch
r-r.matlab	3.6.2	Methods readMat() and writeMat() for reading and writing MAT files. For user with MATLAB v6 or newer installed (either locally or on a remote host), the package also provides methods for controlling MATLAB (trademark) via R and sending and retrieving data between R and MATLAB. / LGPL-2.1	noarch
r-r.methodss3	1.7.1	Methods that simplify the setup of S3 generic functions and S3 methods. Major effort has been made in making definition of methods as simple as possible with a minimum of maintenance for package developers. For example, generic functions are created automatically, if missing, and naming conflict are automatically solved, if possible. The method setMethodS3() is a good start for those who in the future may want to migrate to S4. This is a cross-platform package implemented in pure R that generates standard S3 methods. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-r.oo	1.22.0	Methods and classes for object-oriented programming in R with or without references. Large effort has been made on making definition of methods as simple as possible with a minimum of maintenance for package developers. The package has been developed since 2001 and is now considered very stable. This is a cross-platform package implemented in pure R that defines standard S3 classes without any tricks. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-r.utils	2.8.0	Utility functions useful when programming and developing R packages. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-r0	1.2.6	Estimation of reproduction numbers for disease outbreak, based on incidence data. The R0 package implements several documented methods. It is therefore possible to compare estimations according to the methods used. Depending on the methods requested by user, basic reproduction number (commonly denoted as R0) or real-time reproduction number (referred to as R(t)) is computed, along with a 95% Confidence Interval. Plotting outputs will give different graphs depending on the methods requested : basic reproductive number estimations will only show the epidemic curve (collected data) and an adjusted model, whereas real-time methods will also show the R(t) variations throughout the outbreak time period. Sensitivity analysis tools are also provided, and allow for investigating effects of varying Generation Time distribution or time window on estimates. / GPL-2	noarch
r-r1magic	0.3.2	Utilities for sparse signal recovery suitable for compressed sensing. L1, L2 and TV penalties, DFT basis matrix, simple sparse signal generator, mutual cumulative coherence between two matrices and examples, Lp complex norm, scaling back regression coefficients. / GPL-3	noarch
r-r2admb	0.7.16	A series of functions to call 'AD Model Builder' (i.e., compile and run models) from within R, read the results back into R as 'admb' objects, and provide standard accessors (i.e. coef(), vcov(), etc.) / GPL-3	noarch
r-r2beat	1.0.0	Multivariate optimal allocation for different domains in one and two stages stratified sample design. R2BEAT extends the Neyman (1934) <doi:10.2307/2342192> – Tschuprow (1923) allocation method to the case of several variables, adopting a generalization of the Bethel's proposal (1989). R2BEAT develops this methodology but, moreover, it allows to determine the sample allocation in the multivariate and multi-domains case of estimates for two-stage stratified samples. / EUPL	noarch
r-r2d2	1.0.0	This package provides generic functions to analyze the distribution of two continuous variables: 'conf2d' to calculate a smooth empirical confidence region, and 'freq2d' to calculate a frequency distribution. / GPL-2	noarch
r-r2d3	0.2.3	Suite of tools for using 'D3', a library for producing dynamic, interactive data visualizations. Supports translating objects into 'D3' friendly data structures, rendering 'D3' scripts, publishing 'D3' visualizations, incorporating 'D3' in R Markdown, creating interactive 'D3' applications with Shiny, and distributing 'D3' based 'htmlwidgets' in R packages. / BSD_3_clause file LICENSE	noarch
r-r2dgc	1.0.3	Provides functions for aligning 2D gas chromatography mass spectrometry derived metabolite peaks obtained from primary processing and generates an alignment table that allows for a comparison of common peaks across samples and metabolite identification. Publication describing the package in detail is available at the following citation: Ryne C. Ramaker, Emily Gordon, Sara J. Cooper (2017) <doi:10.1101/179168>. / MIT	noarch
r-r2dt	0.1	Some heavily used base R functions are reconstructed to also be compliant to data.table objects. Also, some general helper functions that could be of interest for working with data.table objects are included. / GPL-3	noarch
r-r2html	2.3.2	Includes HTML function and methods to write in an HTML file. Thus, making HTML reports is easy. Includes a function that allows redirection on the fly, which appears to be very useful for teaching purpose, as the student can keep a copy of the produced output to keep all that he did during the course. Package comes with a vignette describing how to write HTML reports for statistical analysis. Finally, a driver for 'Sweave' allows to parse HTML flat files containing R code and to automatically write the corresponding outputs (tables and graphs). / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-r2openbugs	3.2.3	Using this package, it is possible to call a BUGS model, summarize inferences and convergence in a table and graph, and save the simulations in arrays for easy access in R. / GPL-2	noarch
r-r2pmml	0.23.0	R wrapper for the JPMML-R library < https://github.com/jpmml/jpmml-r >, which converts R models to Predictive Model Markup Language (PMML). / AGPL-3	noarch
r-r2stl	1.0.0	r2stl, R package for visualizing data using a 3D printer Package r2stl converts R data to STL (stereolithography) files that can be used to feed a 3-dimensional printer. The 3-dimensional output from an R function can be materialized into a solid surface in a plastic material, therefore allowing more detailed examination. There are many possible uses for this new R tool, such as to examine mathematical expressions with very irregular shapes, to aid teaching people with impaired vision, to create raised relief maps from digital elevation maps (DEMs), to bridge the gap between mathematical tools and rapid prototyping, and many more. Ian Walker created the function r2stl and Jose' Gama assembled the package. / CC BY-NC-SA 3.0	noarch
r-r2winbugs	2.1.2	Invoke a 'BUGS' model in 'OpenBUGS' or 'WinBUGS', a class bugs for 'BUGS' results and functions to work with that class. Function write.model() allows a 'BUGS' model file to be written. The class and auxiliary functions could be used with other MCMC programs, including 'JAGS'. / GPL-2	noarch
r-r3port	0.1.1	Create and combine HTML and PDF reports from within R. Possibility to design tables and listings for reporting and also include R plots. / GPL-2	noarch
r-r4couchdb	0.7.5	Provides a collection of functions for basic database and document management operations such as add, get, list access or delete. Every cdbFunction() gets and returns a list() containing the connection setup. Such a list can be generated by cdbIni(). / MIT	noarch
r-r6	2.4.0	Creates classes with reference semantics, similar to R's built-in reference classes. Compared to reference classes, R6 classes are simpler and lighter-weight, and they are not built on S4 classes so they do not require the methods package. These classes allow public and private members, and they support inheritance, even when the classes are defined in different packages. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-r62s3	1.3.1	After defining an R6 class, R62S3 is used to automatically generate optional S3/S4 generics and methods for dispatch. Also allows piping for R6 objects. / MIT	noarch
r-r6ds	1.2.0	Provides reference classes implementing some useful data structures. The package implements these data structures by using the reference class R6. Therefore, the classes of the data structures are also reference classes which means that their instances are passed by reference. The implemented data structures include stack, queue, double-ended queue, doubly linked list, set, dictionary and binary search tree. See for example < https://en.wikipedia.org/wiki/Data_structure > for more information about the data structures. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-radanalysis	0.5.5	It has tools for normalization of rank abundance distributions (RAD) to a desired number of ranks using MaxRank Normalization method. RADs are commonly used in biology/ecology and mathematically equivalent to complementary cumulative distributions (CCDFs) which are used in physics, linguistics and sociology and more generally in data science. / GPL-3	noarch
r-radar	1.0.0	Fundamental formulas for Radar, for attenuation, range, velocity, effectiveness, power, scatter, doppler, geometry, radar equations, etc. Based on Nick Guy's Python package PyRadarMet / GPL-3	noarch
r-radarboxplot	1.0.0	Creates the radar-boxplot, a plot that was created by the author during his doctoring in forest resources. The radar-boxplot is a visualization feature suited for multivariate classification/clustering. It provides an intuitive deep understanding of the data. / MIT	noarch
r-radarchart	0.3.1	Create interactive radar charts using the 'Chart.js' 'JavaScript' library and the 'htmlwidgets' package. 'Chart.js' < http://www.chartjs.org/ > is a lightweight library that supports several types of simple chart using the 'HTML5' canvas element. This package provides an R interface specifically to the radar chart, sometimes called a spider chart, for visualising multivariate data. / MIT	noarch
r-raddata	1.0.0	Nuclear Decay Data for Dosimetric Calculations from the International Commission on Radiological Protection from ICRP Publication 107. Ann. ICRP 38 (3). Eckerman, Keith and Endo, Akira 2008 < doi:10.1016/j.icrp.2008.10.004 > < http://www.icrp.org/publication.asp?id=ICRP%20Publication%20107 >. This is a database of the physical data needed in calculations of radionuclide-specific protection and operational quantities. The data is prescribed by the ICRP, the international authority on radiation dose standards, for estimating dose from the intake of or exposure to radionuclides in the workplace and the environment. The database contains information on the half-lives, decay chains, and yields and energies of radiations emitted in nuclear transformations of 1252 radionuclides of 97 elements. / GPL-2	noarch
r-radiosonde	1.4	RadioSonde is a collection of programs for reading and plotting SKEW-T, log p diagrams and wind profiles for data collected by radiosondes (the typical weather balloon-borne instrument), which we will call flights, sondes, or profiles throughout the associated documentation. The raw data files are in a common format that has a header followed by specific variables. Use help(ExampleSonde) for the full explanation of the data files. / GPL-2	noarch
r-radjust	0.1.0	Calculates adjusted p-values for the null hypothesis of no replicability across studies for two study designs: (i) a primary and follow-up study, where the features in the follow-up study are selected from the primary study, as described in Bogomolov and Heller (2013) < doi:10.1080/01621459.2013.829002 > and Heller, Bogomolov and Benjamini (2014) < doi:10.1073/pnas.1314814111 >; (ii) two independent studies, where the features for replicability are first selected in each study separately, as described in Bogomolov and Heller (2018) < doi:10.1093/biomet/asv029 >. The latter design is the one encountered in a typical meta-analysis of two studies, but the inference is for replicability rather than for identifying the features that are non-null in at least one study. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-radviz	0.7.0	An implementation of the radviz projection in R. It enables the visualization of multidimensional data while maintaining the relation to the original dimensions. This package provides functions to create and plot radviz projections, and a number of summary plots that enable comparison and analysis. For reference see Ankerst et al. (1996) < http://citeseer.ist.psu.edu/viewdoc/summary?doi=10.1.1.68.1811 > for original implementation, see Di Caro et al. (2010) <DOI:10.1007/978-3-642-13672-6_13> for the original method for dimensional anchor arrangements. / CC BY-NC-SA 4.0	noarch
r-radwords	0.1.18	Aims at loading Google Adwords data into R. Adwords is an online advertising service that enables advertisers to display advertising copy to web users (see < https://developers.google.com/adwords/ > for more information). Therefore the package implements three main features. First, the package provides an authentication process for R with the Google Adwords API (see < https://developers.google.com/adwords/api/ > for more information) via OAuth2. Second, the package offers an interface to apply the Adwords query language in R and query the Adwords API with ad-hoc reports. Third, the received data are transformed into suitable data formats for further data processing and data analysis. / MIT	noarch
r-rafalib	1.0.0	A series of shortcuts for routine tasks originally developed by Rafael A. Irizarry to facilitate data exploration. / Artistic-2.0	noarch
r-rahrefs	0.1.4	Enables downloading detailed reports from < https://ahrefs.com > about backlinks from pointing to website, provides authentication with an API key as well as ordering, grouping and filtering functionalities. / MIT	noarch
r-rainfallerosivityfactor	0.1.0	Determination of rainfall-runoff erosivity factor. / GPL-2	noarch
r-rainfarmr	0.1	An implementation of the RainFARM (Rainfall Filtered Autoregressive Model) stochastic precipitation downscaling method (Rebora et al. (2006) <doi:10.1175/JHM517.1>). Adapted for climate downscaling according to D'Onofrio et al. (2018) <doi:10.1175/JHM-D-13-096.1> and for complex topography as in Terzago et al. (2018) <doi:10.5194/nhess-18-2825-2018>. The RainFARM method is based on the extrapolation to small scales of the Fourier spectrum of a large-scale precipitation field, using a fixed logarithmic slope and random phases at small scales, followed by a nonlinear transformation of the resulting linearly correlated stochastic field. RainFARM allows to generate ensembles of spatially downscaled precipitation fields which conserve precipitation at large scales and whose statistical properties are consistent with the small-scale statistics of observed precipitation, based only on knowledge of the large-scale precipitation field. / Apache License 2.0	noarch
r-raltmetric	0.7.0	Provides a programmatic interface to the citation information and alternate metrics provided by 'Altmetric'. Data from Altmetric allows researchers to immediately track the impact of their published work, without having to wait for citations. This allows for faster engagement with the audience interested in your work. For more information, visit < https://www.altmetric.com/ >. / MIT	noarch
r-ramble	0.1.1	Parser generator for R using combinatory parsers. It is inspired by combinatory parsers developed in Haskell. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-ramchoice	1.1	It is widely documented in psychology, economics and other disciplines that socio-economic agent may not pay full attention to all available alternatives, rendering standard revealed preference theory invalid. This package implements the estimation and inference procedures of Cattaneo, Ma, Masatlioglu and Suleymanov (2019) <arXiv:1712.03448>, which utilizes standard choice data to partially identify and estimate a decision maker's preference. For inference, several simulation-based critical values are provided. / GPL-2	noarch
r-ramify	0.3.3	Additional matrix functionality for R including: (1) wrappers for the base matrix function that allow matrices to be created from character strings and lists (the former is especially useful for creating block matrices), (2) better printing of large matrices via the generic pretty print function, and (3) a number of convenience functions for users more familiar with other scientific languages like 'Julia', 'Matlab'/'Octave', or 'Python' 'NumPy'. / GPL-2	noarch
r-rampath	0.4	We rewrite of RAMPpath software developed by John McArdle and Steven Boker as an R package. In addition to performing regular SEM analysis through the R package lavaan, RAMPpath has unique features. First, it can generate path diagrams according to a given model. Second, it can display path tracing rules through path diagrams and decompose total effects into their respective direct and indirect effects as well as decompose variance and covariance into individual bridges. Furthermore, RAMPpath can fit dynamic system models automatically based on latent change scores and generate vector field plots based upon results obtained from a bivariate dynamic system. Starting version 0.4, RAMPpath can conduct power analysis for both univariate and bivariate latent change score models. / GPL-2	noarch
r-randcorr	1.0	Implements the algorithm by Pourahmadi and Wang (2015) <doi:10.1016/j.spl.2015.06.015> for generating a random $p \times p$ correlation matrix. Briefly, the idea is to represent the correlation matrix using Cholesky factorization and $p(p-1)/2$ hyperspherical coordinates (i.e., angles), sample the angles from a particular distribution and then convert to the standard correlation matrix form. The angles are sampled from a distribution with pdf proportional to $\sin^k(\theta)$ ($0 < \theta < \pi$, $k \geq 1$) using the efficient sampling algorithm described in Enes Makalic and Daniel F. Schmidt (2018) <arXiv:1809.05212>. / GPL-3	noarch
r-randgeo	0.3.0	Generate random positions (latitude/longitude), Well-known text ('WKT') points or polygons, or 'GeoJSON' points or polygons. / MIT	noarch
r-randmeta	0.1.0	A novel numerical algorithm that provides functionality for estimating the exact 95% confidence interval of the location parameter in the random effects model, and is much faster than the naive method. Works best when the number of studies is between 6-20. / GPL-2	noarch
r-random	0.2.6	The true random number service provided by the RANDOM.ORG website created by Mads Haahr samples atmospheric noise via radio tuned to an unused broadcasting frequency together with a skew correction algorithm due to John von Neumann. More background is available in the included vignette based on an essay by Mads Haahr. In its current form, the package offers functions to retrieve random integers, randomized sequences and random strings. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-randomforest	4.6_14	Classification and regression based on a forest of trees using random inputs, based on Breiman (2001) <DOI:10.1023/A:1010933404324>. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-randomglm	1.02_1	The package implements a bagging predictor based on general linear models / GPL-2	noarch
r-randomizebe	0.3_5	Contains a function to randomize subjects, patients in groups of sequences (treatment sequences). If a blocksize is given, the randomization will be done within blocks. The randomization may be controlled by a Wald-Wolfowitz runs test. Functions to obtain the p-value of that test are included. The package is mainly intended for randomization of bioequivalence studies but may be used also for other clinical crossover studies. Contains two helper functions sequences() and williams() to get the sequences of commonly used designs in BE studies. / GPL (>= 2.0)	noarch
r-randtests	1.0	Several non parametric randomness tests for numeric sequences / GPL-2	noarch
r-rangemodlr	1.0.4	Generates expected values of species richness, with continuous or scattered ranges, for data across one or two dimensions. / GPL-2	noarch
r-ranger	0.11.2	A fast implementation of Random Forests, particularly suited for high dimensional data. Ensembles of classification, regression, survival and probability prediction trees are supported. Data from genome-wide association studies can be analyzed efficiently. In addition to data frames, datasets of class 'gwaa.data' (R package 'GenABEL') and 'dgCMatrx' (R package 'Matrix') can be directly analyzed. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-rankfd	0.0.3	The rankFD() function calculates the Wald-type statistic (WTS) and the ANOVA-type statistic (ATS) for nonparametric factorial designs, e.g., for count, ordinal or score data in a crossed design with an arbitrary number of factors. / GPL-2 GPL-3	noarch
r-rankhazard	1.1.0	Rank-hazard plots Karvanen and Harrell (2009) <DOI:10.1002/sim.3591> visualize the relative importance of covariates in a proportional hazards model. The key idea is to rank the covariate values and plot the relative hazard as a function of ranks scaled to interval [0,1]. The relative hazard is plotted in respect to the reference hazard, which can be e.g. the hazard related to the median of the covariate. / GPL-2	noarch
r-rankingproject	0.1.1	Functions to generate plots and tables for comparing independently- sampled populations. Companion package to A Primer on Visualizations for Comparing Populations, Including the Issue of Overlapping Confidence Intervals by Wright, Klein, and Wieczorek (2017, in press). / GPL-2	noarch
r-rankresponse	3.1.1	Methods for ranking responses of a single response question or a multiple response question / GPL-2	noarch
r-rap	1.1	To find the reversal association between variables. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rapiclient	0.1.2	Access services specified in OpenAPI (formerly Swagger) format. It is not a code generator. Client is generated dynamically as a list of R functions. / MIT	noarch
r-rapidjsonr	1.1	Provides JSON parsing capability through the ‘Rapidjson’ ‘C’ header-only library. / MIT	noarch
r-rapidxmlr	0.1.0	Provides XML parsing capability through the ‘Rapidxml’ ‘C’ header-only library. / MIT	noarch
r-rappdirs	0.3.1	An easy way to determine which directories on the users computer you should use to save data, caches and logs. A port of Python’s ‘Appdirs’ (url{https://github.com/ActiveState/appdirs}) to R. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-raptor	1.0.0	Performs wood cell anatomical data analyses on spatially explicit xylem (tracheids) datasets derived from thin sections of woody tissue. The package includes functions for visualisation, detection and alignment of continuous tracheid radial file (defined as rows) and individual tracheid position within an annual ring of coniferous species. This package is designed to be used with elaborate cell output, e.g. as provided with ROXAS (von Arx & Carrer, 2014 <doi:10.1016/j.dendro.2013.12.001>). The package has been validated for Picea abies, Larix Siberica, Pinus cembra and Pinus sylvestris. / GPL-2	noarch
r-rarity	1.3_6	Allows calculation of rarity weights for species and indices of rarity for assemblages of species according to different methods (Leroy et al. 2012, Insect. Conserv. Divers. 5:159-168 <doi:10.1111/j.1752-4598.2011.00148.x>; Leroy et al. 2013, Divers. Distrib. 19:794-803 <doi:10.1111/ddi.12040>). / GPL (>= 2.0)	noarch
r-rasciidoc	2.0.0	Inspired by Karl Broman’s reader on using ‘knitr’ with ‘asciidoc’ (< http://kbroman.org/knitr_knutshell/pages/asciidoc.html >), this is merely a wrapper to ‘knitr’ and ‘asciidoc’. / BSD_2_clause	noarch
r-raster	2.8_1	Reading, writing, manipulating, analyzing and modeling of gridded spatial data. The package implements basic and high-level functions. Processing of very large files is supported. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
r-rasterize	0.1	Provides R functions to selectively rasterize components of ‘grid’ output. / GPL-3	noarch
r-rasterlist	0.5.8	A S4 class has been created such that complex operations can be executed on each cells of a raster map. The raster of objects contains the traditional raster map with the addition of a list of generic objects: one object for each raster cells. It allows to write few lines of R code for complex map algebra. Two environmental applications about frequency analysis of raster map of precipitation and creation of a raster map of soil water retention curves have been presented. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-rastervis</code>	0.46	Methods for enhanced visualization and interaction with raster data. It implements visualization methods for quantitative data and categorical data, both for univariate and multivariate rasters. It also provides methods to display spatiotemporal rasters, and vector fields. See the website for examples. / GPL-3	noarch
<code>r-ratedistortion</code>	1.01	An implementation of routines for solving rate-distortion problems. Rate-distortion theory is a field within information theory that examines optimal lossy compression. That is, given that some information must be lost, how can a communication channel be designed that minimizes the cost of communication error? Rate-distortion theory is concerned with the optimal (minimal cost) solution to such tradeoffs. An important tool for solving rate-distortion problems is the Blahut algorithm, developed by Richard Blahut and described in: . Blahut, R. E. (1972). Computation of channel capacity and rate-distortion functions. IEEE Transactions on Information Theory, IT-18(4), 460-473. . This package implements the basic Blahut algorithm, and additionally contains a number of ‘helper’ functions, including a routine for searching for an information channel that minimizes cost subject to a constraint on information rate. / GPL-2	noarch
<code>r-ratelimitr</code>	0.4.1	Allows to limit the rate at which one or more functions can be called. / MIT	noarch
<code>r-rateratio.test</code>	1.0.2	A function which performs exact rate ratio tests and returns an object of class <code>htest</code> . / GPL-3	noarch
<code>r-raters</code>	2.0.1	The kappa statistic implemented by Fleiss is a very popular index for assessing the reliability of agreement among multiple observers. It is used both in the psychological and in the psychiatric field. Other fields of application are typically medicine, biology and engineering. Unfortunately, the kappa statistic may behave inconsistently in case of strong agreement between raters, since this index assumes lower values than it would have been expected. We propose a modification kappa implemented by Fleiss in case of nominal and ordinal variables. Monte Carlo simulations are used both to testing statistical hypotheses and to calculating percentile bootstrap confidence intervals based on proposed statistic in case of nominal and ordinal data. / GPL-2	noarch
<code>r-ratesci</code>	0.3.0	Computes confidence intervals for the rate (or risk) difference (‘RD’) or rate ratio (or relative risk, ‘RR’) for binomial proportions or Poisson rates, or for odds ratio (‘OR’, binomial only). Also confidence intervals for a single binomial or Poisson rate, and intervals for matched pairs. Includes skewness-corrected asymptotic score (‘SCAS’) methods, which have been developed in Laud (2017) <doi:10.1002/pst.1813> from Miettinen & Nurminen (1985) <doi:10.1002/sim.4780040211> and Gart & Nam (1988) <doi:10.2307/2531848>. Also includes MOVER methods (Method Of Variance Estimates Recovery) for all contrasts, derived from the Newcombe method but using equal-tailed Jeffreys intervals, and generalised for Bayesian applications incorporating prior information. So-called ‘exact’ methods for strictly conservative coverage are approximated using continuity corrections. Also includes methods for stratified calculations (e.g. meta-analysis), either assuming fixed effects or incorporating stratum heterogeneity. / GPL-3	noarch
<code>r-ratios</code>	1.2.0	Calculation of ratios between two data sets containing environmental data like element concentrations by different methods. Additionally plant element concentrations can be corrected for adhering particles (soil, airborne dust). / GPL-3	noarch
<code>r-rattle.data</code>	1.0.2	Contains the datasets used as default examples by the rattle package. The datasets themselves can be used independently of the rattle package to illustrate analytics, data mining, and data science tasks. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-raw	0.1.6	In order to facilitate R instruction for actuaries, we have organized several sets of publicly available data of interest to non-life actuaries. In addition, we suggest a set of packages, which most practicing actuaries will use routinely. Finally, there is an R markdown skeleton for basic reserve analysis. / CC0	noarch
r-rbenchmark	1.0.0	rbenchmark is inspired by the Perl module Benchmark, and is intended to facilitate benchmarking of arbitrary R code. The library consists of just one function, benchmark, which is a simple wrapper around system.time. Given a specification of the benchmarking process (counts of replications, evaluation environment) and an arbitrary number of expressions, benchmark evaluates each of the expressions in the specified environment, replicating the evaluation as many times as specified, and returning the results conveniently wrapped into a data frame. / GPL-2	noarch
r-rbiouml	1.8	Functions for connecting to BioUML server, querying BioUML repository and launching BioUML analyses. / GPL-2	noarch
r-rbit	1.0.0	A simple implementation of Binary Indexed Tree by R. The BinaryIndexedTree class supports construction of Binary Indexed Tree from a vector, update of a value in the vector and query for the sum of a interval of the vector. / MIT	noarch
r-rbitcoin	0.9.2	Utilities related to Bitcoin. Unified markets API interface (bitstamp, kraken, btce, bitmarket). Both public and private API calls. Integration of data structures for all markets. Support SSL. Read Rbitcoin documentation (command: ?btc) for more information. / MIT	noarch
r-rbitcoinchartsapi	1.0.4	An R package for the BitCoinCharts.com API. / LGPL-3	noarch
r-rbldatalicense	0.2.1	R interface to access prices and market data with the 'Bloomberg Data License' service from < https://www.bloomberg.com/professional/product/data-license/ >. As a prerequisite, a valid Data License from 'Bloomberg' is needed together with the corresponding SFTP credentials and whitelisting of the IP from which accessing the service. This software and its author are in no way affiliated, endorsed, or approved by 'Bloomberg' or any of its affiliates. 'Bloomberg' is a registered trademark. / GPL-3	noarch
r-rbmnn	0.9_2	Creation, manipulation, simulation of linear Gaussian Bayesian networks from text files and more... / GPL-2	noarch
r-rbokeh	0.6.3	A native R plotting library that provides a flexible declarative interface for creating interactive web-based graphics, backed by the Bokeh visualization library < http://bokeh.pydata.org/ >. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rbtc	0.1_6	Implementation of the RPC-JSON API for Bitcoin and utility functions for address creation and content analysis of the blockchain. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rbtt	0.1.0	Tu & Zhou (1999) <doi:10.1002/(SICI)1097-0258(19991030)18:20%3C2749::AID-SIM195%3E3.0.CO;2-C> showed that comparing the means of populations whose data-generating distributions are non-negative with excess zero observations is a problem of great importance in the analysis of medical cost data. In the same study, Tu & Zhou discuss that it can be difficult to control type-I error rates of general-purpose statistical tests for comparing the means of these particular data sets. This package allows users to perform a modified bootstrap-based t-test that aims to better control type-I error rates in these situations. / GPL-3	noarch
r-rca	2.0	Relational Class Analysis (RCA) is a method for detecting heterogeneity in attitudinal data (as described in Goldberg A., 2011, Am. J. Soc, 116(5)). / GPL-2	noarch
r-rcane	1.0	There are different numeric optimizations which are used in order to estimate coefficients in models such as linear regression and neural networks. This package covers parameter estimation in linear regression using different methods such as batch gradient descent, stochastic gradient descent, minibatch gradient descent and coordinate descent. Kiwiel, Krzysztof C (2001) <doi:10.1007/PL00011414> Yu Nesterov (2004) <ISBN:1-4020-7553-7> Ferguson, Thomas S (1982) <doi:10.1080/01621459.1982.10477894> Zeiler, Matthew D (2012) <arXiv:1212.5701> Wright, Stephen J (2015) <arXiv:1502.04759>. / MIT	noarch
r-rcapture	1.4.2	Estimation of abundance and other of demographic parameters for closed populations, open populations and the robust design in capture-recapture experiments using loglinear models. / GPL-2	noarch
r-rcarbon	1.2.0	Enables the calibration and analysis of radiocarbon dates, often but not exclusively for the purposes of archaeological research. It includes functions not only for basic calibration, uncalibration, and plotting of one or more dates, but also a statistical framework for building demographic and related longitudinal inferences from aggregate radiocarbon date lists, including: Monte-Carlo simulation test (Timpson et al 2014 <doi:10.1016/j.jas.2014.08.011>), random mark permutation test (Crema et al 2016 <doi:10.1371/journal.pone.0154809>) and spatial permutation tests (Crema, Bevan, and Shennan 2017 <doi:10.1016/j.jas.2017.09.007>). / GPL-2	noarch
r-rcarto	0.8	This package makes some maps using shapefiles and dataframes. Five kinds of maps are available : proportionnal circles, proportionnal circles colored by a discretized quantitative variable, proportionnal circles colored by the modalities of a qualitative variable, choropleth and typology. / GPL (>= 2.0)	noarch
r-rcbalance	1.8.5	Tools for large, sparse optimal matching of treated units and control units in observational studies. Provisions are made for refined covariate balance constraints, which include fine and near-fine balance as special cases. Matches are optimal in the sense that they are computed as solutions to network optimization problems rather than greedy algorithms. / MIT	noarch
r-rcsubset	1.1.4	Tools for optimal subset matching of treated units and control units in observational studies, with support for refined covariate balance constraints, (including fine and near-fine balance as special cases). A close relative is the 'rcbalance' package. / MIT	noarch
r-rcc	1.0.0	Functions to implement the parametric and non-parametric bootstrap confidence interval methods described in Morrison and Simon (2017) <arXiv:1702.06986>. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rcklibs	2.0	An R interface to the Chemistry Development Kit, a Java library for chemoinformatics. Given the size of the library itself, this package is not expected to change very frequently. To make use of the CDK within R, it is suggested that you use the ‘rckd’ package. Note that it is possible to directly interact with the CDK using ‘rJava’. However ‘rckd’ exposes functionality in a more idiomatic way. The CDK library itself is released as LGPL and the sources can be obtained from https://github.com/cdk/cdk . / LGPL-3	noarch
r-rceim	0.3	An implementation of a stochastic heuristic method for performing multidimensional function optimization. The method is inspired in the Cross-Entropy Method. It does not relies on derivatives, neither imposes particularly strong requirements into the function to be optimized. Additionally, it takes profit from multi-core processing to enable optimization of time-consuming functions. / GPL-2	noarch
r-rclldata	1.3.2	Example dataset for ‘Rcell’ package. Contains images and cell data object. / GPL-2	noarch
r-rcereal	1.2.1	To facilitate using ‘cereal’ with Rcpp. ‘cereal’ is a header-only C11 serialization library. ‘cereal’ takes arbitrary data types and reversibly turns them into different representations, such as compact binary encodings, XML, or JSON. ‘cereal’ was designed to be fast, light-weight, and easy to extend - it has no external dependencies and can be easily bundled with other code or used standalone. Please see http://uscilab.github.io/cereal for more information. / BSD_2_clause	noarch
r-rcgmin	2013.0	Conjugate gradient minimization of nonlinear functions with box constraints incorporating the Dai/Yuan update. This implementation should be used in place of the CG algorithm of the optim() function. / GPL-2	noarch
r-rchallenge	1.3.0	A simple data science challenge system using R Markdown and Dropbox https://www.dropbox.com/ . It requires no network configuration, does not depend on external platforms like e.g. Kaggle https://www.kaggle.com/ and can be easily installed on a personal computer. / GPL-2	noarch
r-rcheology	3.6.1	Provides a dataset of functions in all base packages of R versions 1.0.1 onwards. / CC0	noarch
r-rchoicedialogs	1.0.6	Collection of portable choice dialog widgets / LGPL-2.1	noarch
r-rcircos	1.2.1	A simple and flexible way to generate Circos 2D track plot images for genomic data visualization is implemented in this package. The types of plots include: heatmap, histogram, lines, scatterplot, tiles and plot items for further decorations include connector, link (lines and ribbons), and text (gene) label. All functions require only R graphics package that comes with R base installation. / GPL-2	noarch
r-rcites	1.0.1	A programmatic interface to the Species https://speciesplus.net/ database via the Species/CITES Checklist API https://api.speciesplus.net/ . / MIT	noarch
r-rclean	1.0.0	To create clearer, more concise code provides this toolbox helps coders to isolate the essential parts of a script that produces a chosen result, such as an object, tables and figures written to disk and even warnings and errors. This work was funded by US National Science Foundation grant SSI-1450277 for applications of End-to-End Data Provenance. / GPL-3	noarch
r-rclinicalcodes	1.0.1	R tools for integrating with the www.clinicalcodes.org web repository / GPL-2	noarch
r-rclipboard	0.1.2	Leverages the functionality of ‘clipboard.js’, a JavaScript library for HTML5-based copy to clipboard from web pages (see https://clipboardjs.com for more information), and provides a reactive copy-to-clipboard UI button component, called ‘rclipButton’, for ‘shiny’ R applications. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rcclone	1.0.2	R version of ‘GenClone’ (a computer program to analyse genotypic data, test for clonality and describe spatial clonal organization, Arnaud-Haond & Belkhir 2007, < http://wwz.ifremer.fr/clonix/content/download/68205/903914/file/GenClone2.0.setup.zip >), this package allows clone handling as ‘GenClone’ does, plus the possibility to work with several populations, Multi-Locus Lineages (MLL) custom definition and use, and p-value calculation for psex statistic (probability of originating from distinct sexual events) and psex_Fis statistic (taking account of Hardy-Weinberg equilibrium departure) as ‘MLGsim’/‘MLGsim2’ (a program for detecting clones using a simulation approach, Stenberg et al. 2003). / GPL (>= 2.0)	noarch
r-rcma	1.1	Tool for providing access to the Java version ‘CMAEvolutionStrategy’ of Nikolaus Hansen. ‘CMA-ES’ is the Covariance Matrix Adaptation Evolution Strategy, see https://www.lri.fr/~hansen/cmaes_inmatlab.html#java . / GPL-3	noarch
r-rcmdcheck	1.3.2	Run ‘R CMD check’ from ‘R’ programmatically, and capture the results of the individual checks. / MIT file LICENSE	noarch
r-rcolombos	2.0.2	Provides programmatic access to Colombos, a web based interface for exploring and analyzing comprehensive organism-specific cross-platform expression compendia of bacterial organisms. / GPL-3	noarch
r-rcolorbrewer	1.1_2	Provides color schemes for maps (and other graphics) designed by Cynthia Brewer as described at http://colorbrewer2.org / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rconics	1.0	Solve some conic related problems (intersection of conics with lines and conics, arc length of an ellipse, polar lines, etc.). / GPL-2	noarch
r-rcorpora	2.0.0	A collection of small text corpora of interesting data. It contains all data sets from ‘dariusk/corpora’. Some examples: names of animals: birds, dinosaurs, dogs; foods: beer categories, pizza toppings; geography: English towns, rivers, oceans; humans: authors, US presidents, occupations; science: elements, planets; words: adjectives, verbs, proverbs, US president quotes. / CC0	noarch
r-rcpp	1.0.1	The ‘Rcpp’ package provides R functions as well as C classes which offer a seamless integration of R and C. Many R data types and objects can be mapped back and forth to C equivalents which facilitates both writing of new code as well as easier integration of third-party libraries. Documentation about ‘Rcpp’ is provided by several vignettes included in this package, via the ‘Rcpp Gallery’ site at < http://gallery.rcpp.org >, the paper by Eddelbuettel and Francois (2011, < doi:10.18637/jss.v040.i08 >), the book by Eddelbuettel (2013, < doi:10.1007/978-1-4614-6868-4 >) and the paper by Eddelbuettel and Balamuta (2017, < doi:10.7287/peerj.preprints.3188v1 >); see ‘citation(Rcpp)’ for details. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-rcpp11	3.1.2.0	Rcpp11 includes a header only C11 library that facilitates integration between R and modern C. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rcpparmadillo	0.9.3002	'Armadillo' is a templated C linear algebra library (by Conrad Sanderson) that aims towards a good balance between speed and ease of use. Integer, floating point and complex numbers are supported, as well as a subset of trigonometric and statistics functions. Various matrix decompositions are provided through optional integration with LAPACK and ATLAS libraries. The 'RcppArmadillo' package includes the header files from the templated 'Armadillo' library. Thus users do not need to install 'Armadillo' itself in order to use 'RcppArmadillo'. From release 7.800.0 on, 'Armadillo' is licensed under Apache License 2; previous releases were under licensed as MPL 2.0 from version 3.800.0 onwards and LGPL-3 prior to that; 'RcppArmadillo' (the 'Rcpp' bindings/bridge to Armadillo) is licensed under the GNU GPL version 2 or later, as is the rest of 'Rcpp'. Note that Armadillo requires a fairly recent compiler; for the g family at least version 4.6.* is required. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-rcppeigen	0.3.3.50	and 'Eigen' integration using 'Rcpp'. 'Eigen' is a C template library for linear algebra: matrices, vectors, numerical solvers and related algorithms. It supports dense and sparse matrices on integer, floating point and complex numbers, decompositions of such matrices, and solutions of linear systems. Its performance on many algorithms is comparable with some of the best implementations based on 'Lapack' and level-3 'BLAS'. The 'RcppEigen' package includes the header files from the 'Eigen' C template library (currently version 3.3.4). Thus users do not need to install 'Eigen' itself in order to use 'RcppEigen'. Since version 3.1.1, 'Eigen' is licensed under the Mozilla Public License (version 2); earlier version were licensed under the GNU LGPL version 3 or later. 'RcppEigen' (the 'Rcpp' bindings/bridge to 'Eigen') is licensed under the GNU GPL version 2 or later, as is the rest of 'Rcpp'. / GPL (>= 2) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-rcppprogress	0.4.1	Allows to display a progress bar in the R console for long running computations taking place in c code, and support for interrupting those computations even in multithreaded code, typically using OpenMP. / GPL (>= 3)	noarch
r-rcpproll	0.3.0	Provides fast and efficient routines for common rolling / windowed operations. Routines for the efficient computation of windowed mean, median, sum, product, minimum, maximum, standard deviation and variance are provided. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-rcppthread	0.5.3	Provides a C11-style thread class and thread pool that can safely be interrupted from R; see, Nagler (2018) <arXiv:1811.00450>. / MIT	noarch
r-rcppxptrutils	0.1.1	Provides the means to compile user-supplied C functions with 'Rcpp' and retrieve an 'XPtr' that can be passed to other C components. / MIT	noarch
r-rcreds	0.6.6	Tools to write a list of credentials to an encrypted file and later read from that file into R. The goal is to have a useful alternative to including username/passwords as part of a script or even stored in the clear in a separate text file. Additional tools provided which are specific for connecting to a database. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rcriteo	1.0.2	Aims at loading Criteo online advertising campaign data into R. Criteo < http://www.criteo.com/ > is an online advertising service that enables advertisers to display commercial ads to web users. The package provides an authentication process for R with the Criteo API < http://kb.criteo.com/advertising/content/5/27/en/api.html >. Moreover, the package features an interface to query campaign data from the Criteo API. The data can be downloaded and will be transformed into a R data frame. / GPL-2 MIT	noarch
r-rcriticor	2.0	Goldwin-Pierre correlogram. Research of critical periods in the past. Integrates a time series in a given window. / GPL-2	noarch
r-rcrypt	0.1.1	Provides easy symmetric file encryption using GPG with cryptographically strong defaults. Only symmetric encryption is supported. GPG is pre-installed with most Linux distributions. Windows users will need to install ‘Gpg4win’ (http://www.gpg4win.org/). OS X users will need to install ‘GPGTools’ (https://gpgtools.org/). / MIT	noarch
r-rcssplot	0.3.0	Provides a means to style plots through cascading style sheets. This separates the aesthetics from the data crunching in plots and charts. / GPL-2	noarch
r-rcube	0.5	Provides simplified methods for managing classic Rubik’s cubes and many other modifications of it (such as NxNxN size cubes, void cubes and 8-coloured cubes - so called octa cubes). Includes functions of handling special syntax for managing such cubes; and different approach to plotting 3D cubes without using external libraries (for example ‘OpenGL’). / GPL-3	noarch
r-rcur	1.3	Functions and objects for CUR matrix decomposition. / GPL-2	noarch
r-rcurl	1.95	Wrapper for ‘libcurl’ < http://curl.haxx.se/libcurl/ > Provides functions to allow one to compose general HTTP requests and provides convenient functions to fetch URIs, get & post forms, etc. and process the results returned by the Web server. This provides a great deal of control over the HTTP/FTP/... connection and the form of the request while providing a higher-level interface than is available just using R socket connections. Additionally, the underlying implementation is robust and extensive, supporting FTP/FTPS/TFTP (uploads and downloads), SSL/HTTPS, telnet, dict, ldap, and also supports cookies, redirects, authentication, etc. / BSD	linux-32, linux-64, osx-64, win-32, win-64
r-rd2md	0.0.2	The native R functionalities only allow PDF exports of reference manuals. This shall be extended by converting the package documentation files into markdown files and combining them into a markdown version of the package reference manual. / GPL-3	noarch
r-rd2roxygen	1.8	Functions to convert Rd to ‘roxygen’ documentation. It can parse an Rd file to a list, create the ‘roxygen’ documentation and update the original R script (e.g. the one containing the definition of the function) accordingly. This package also provides utilities that can help developers build packages using ‘roxygen’ more easily. The ‘formatR’ package can be used to reformat the R code in the examples sections so that the code will be more readable. / GPL-3	noarch
r-rda	1.0.2	Shrunken Centroids Regularized Discriminant Analysis for the classification purpose in high dimensional data. / GPL-2	noarch
r-rdatacanvas	0.1	Provides basic functionalities for writing a module for http://datacanvas.io . The http://datacanvas.io is a big data analytics platform that helps data scientists to build, manage and share data pipelines. / BSD_3_clause	noarch
r-rdataretriever	2.0.0	Provides an R interface to the Data Retriever < http://data-retriever.org/ > via the Data Retriever’s command line interface. The Data Retriever automates the tasks of finding, downloading, and cleaning public datasets, and then stores them in a local database. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rdbnomics	0.4.7	R access to hundreds of millions data series from DBnomics API (< https://db.nomics.world/ >). / AGPL-3	noarch
r-rde	0.1.0	Allows caching of raw data directly in R code. This allows R scripts and R Notebooks to be shared and re-run on a machine without access to the original data. Cached data is encoded into an ASCII string that can be pasted into R code. When the code is run, the data is automatically loaded from the cached version if the original data file is unavailable. Works best for small datasets (a few hundred observations). / GPL-3	noarch
r-rdetools	1.0	The package provides functions for estimating the relevant dimension of a data set in feature spaces, applications to model selection, graphical illustrations and prediction. / GPL-2	noarch
r-rdian	0.1.1	A client library for ‘The Guardian’ (https://www.guardian.com/) and their API, this package allows users to search for Guardian articles and retrieve both the content and metadata. / MIT	noarch
r-rdice	1.0.0	A collection of functions to simulate dice rolls and the like. In particular, experiments and exercises can be performed looking at combinations and permutations of values in dice rolls and coin flips, together with the corresponding frequencies of occurrences. When applying each function, the user has to input the number of times (rolls, flips) to toss the dice. Needless to say, the more the tosses, the more the frequencies approximate the actual probabilities. Moreover, the package provides functions to generate non-transitive sets of dice (like Efron’s) and to check whether a given set of dice is non-transitive with given probability. / GPL-2	noarch
r-rdidq	1.0	The package has many function that helps to perform various quality check on the data. It basically provides many function that helps in performing Extrapolative data analysis. / GPL-2	noarch
r-rdistance	2.1.3	Distance-sampling is a popular method for estimating density and abundance of organisms in ecology. Rdistance contains routines that assist with analysis of distance-sampling data collected on point or line transects. Distance models are specified using regression-like formula (similar to lm, glm, etc.). Abundance routines perform automated bootstrapping and automated detection-function selection. Overall (study area) and site-level (transect or point) abundance estimates are available. A large suite of classical, parametric detection functions are included along with some uncommon parametric functions (e.g., Gamma, negative exponential) and non-parametric smoothed distance functions. Custom (user-defined) detection functions are easily implemented (see vignette). The help files and vignettes have been vetted by multiple authors and tested in workshop settings. / GPL-3	noarch
r-rdnase	1.1_1	Comprehensive toolkit for generating various numerical representation schemes of DNA sequence. The descriptors and similarity scores included are extensively used in bioinformatics and chemogenomics. / GPL-2	noarch
r-rdnb	0.1_3	A wrapper for the ‘Deutsche Nationalbibliothek (German National Library) API’, available at < http://www.dnb.de >. The German National Library is the German central archival library, collecting, archiving, bibliographically classifying all German and German-language publications, foreign publications about Germany, translations of German works, and the works of German-speaking emigrants published abroad between 1933 and 1945. A personal access token is required for usage. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rdocumentation	0.8.2	Wraps around the default help functionality in R. Instead of plain documentation files, documentation will show up as it does on < https://www.rdocumentation.org >, a platform that shows R documentation from ‘CRAN’, ‘GitHub’ and ‘Bioconductor’, together with informative stats to assess the package quality. / GPL-2	noarch
r-rdota2	0.1.6	An R API Client for Valve’s Dota2. RDota2 can be easily used to connect to the Steam API and retrieve data for Valve’s popular video game Dota2. You can find out more about Dota2 at < http://store.steampowered.com/app/570/ >. / MIT	noarch
r-rdrobust	0.99.4	Regression-discontinuity (RD) designs are quasi-experimental research designs popular in social, behavioral and natural sciences. The RD design is usually employed to study the (local) causal effect of a treatment, intervention or policy. This package provides tools for data-driven graphical and analytical statistical inference in RD designs: rdrobust() to construct local-polynomial point estimators and robust confidence intervals for average treatment effects at the cutoff in Sharp, Fuzzy and Kink RD settings, rdbwselect() to perform bandwidth selection for the different procedures implemented, and rdplot() to conduct exploratory data analysis (RD plots). / GPL-2	noarch
r-rdroolsjars	1.0.1	External jars required for package ‘Rdrools’. / Apache License 2.0	noarch
r-rdsm	2.1.1	Provides a threads-type programming environment for R. The package gives the R programmer the clearer, more concise shared memory world view, and in some cases gives superior performance as well. In addition, it enables parallel processing on very large, out-of-core matrices. / GPL-2	linux-64
r-rdstk	1.1	This package provides an R interface to Pete Warden’s Data Science Toolkit. See www.datasciencetoolkit.org for more information. The source code for this package can be found at github.com/rtelmore/RDSTK Happy hacking! / BSD_2_clause	noarch
r-rdstreeboot	1.0	A tree bootstrap method for estimating uncertainty in respondent-driven samples (RDS). Quantiles are estimated by multilevel resampling in such a way that preserves the dependencies of and accounts for the high variability of the RDS process. / GPL-2 GPL-3	noarch
r-reactlog	1.0.0	Building interactive web applications with R is incredibly easy with ‘shiny’. Behind the scenes, ‘shiny’ builds a reactive graph that can quickly become intertwined and difficult to debug. ‘reactlog’ (Schloerke 2019) < doi:10.5281/zenodo.2591517 > provides a visual insight into that black box of ‘shiny’ reactivity by constructing a directed dependency graph of the application’s reactive state at any time point in a reactive recording. / GPL-3	noarch
r-reactr	0.4.1	Make it easy to use ‘React’ in R with ‘htmlwidget’ scaffolds, helper dependency functions, an embedded ‘Babel’ ‘transpiler’, and examples. / MIT	noarch
r-read.gb	1.6	Opens complete record(s) with .gb extension from the NCBI/GenBank Nucleotide database and returns a list containing shaped record(s). These kind of files contains detailed records of DNA samples (locus, organism, type of sequence, source of the sequence. ...). An example of record can be found at < https://www.ncbi.nlm.nih.gov/nuccore/HE799070 >. / GPL (>= 2.0)	noarch
r-readabf	1.0.1	Loads Axon Binary Files (both ‘ABF’ and ‘ABF2’) created by Axon Instruments/Molecular Devices software such as ‘pClamp’. / GPL-3	noarch
r-readbrukerflexdata	1.8.5	Reads data files acquired by Bruker Daltonics’ matrix-assisted laser desorption/ionization-time-of-flight mass spectrometer of the *flex series. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-readbulk	1.1.2	Combine multiple data files from a common directory. The data files will be read into R and bound together, creating a single large data.frame. A general function is provided along with a specific function for data that was collected using the open-source experiment builder ‘OpenSesame’ < http://osdoc.cogsci.nl/ >. / GPL-3	noarch
r-readhac	1.0	Read Acoustic HAC format. / GPL-2	noarch
r-readjdx	0.3.25	Import data written in the JCAMP-DX format. This is an instrument-independent format used in the field of spectroscopy. Examples include IR, NMR, and Raman spectroscopy. See the vignette for background and supported formats. The official JCAMP-DX site is < http://www.jcamp-dx.org/ >. / GPL-3	noarch
r-readmldata	0.9_7	Functions for reading data sets in different formats for testing machine learning tools are provided. This allows to run a loop over several data sets in their original form, for example if they are downloaded from UCI Machine Learning Repository. The data are not part of the package and have to be downloaded separately. / GPL-3	noarch
r-readmnist	1.0.6	You can use the function Read.mnist() to read data and arrange them properly from MNIST dataset (the open handwriting digit database < http://yann.lecun.com/exdb/mnist/ >). With this package, you can conveniently get all of necessary informations and then immediately start to check whether your machine learning algorithm works well. It can automatically recognize the type of dataset and returns the informations in corresponding structure. / GPL-3	noarch
r-readmzxmldata	2.8.1	Functions for reading mass spectrometry data in mzXML format. / GPL-3	noarch
r-readoffice	0.2.2	Reads in text from ‘unstructured’ modern Microsoft Office files (XML based files) such as Word and PowerPoint. This does not read in structured data (from Excel or Access) as there are many other great packages to that do so already. / Unlimited	noarch
r-readr	1.3.1	The goal of ‘readr’ is to provide a fast and friendly way to read rectangular data (like ‘csv’, ‘tsv’, and ‘fwf’). It is designed to flexibly parse many types of data found in the wild, while still cleanly failing when data unexpectedly changes. / GPL (>= 2) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-readxl	1.3.1	Import excel files into R. Supports ‘.xls’ via the embedded ‘libxls’ C library < https://github.com/evanmiller/libxls > and ‘.xlsx’ via the embedded ‘RapidXML’ C library < https://rapidxml.sourceforge.net >. Works on Windows, Mac and Linux without external dependencies. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-realvams	0.4.3	Fits a multivariate value-added model (VAM), see Broatch, Green, and Karl (2018) <doi:10.32614/RJ-2018-033> and Broatch and Lohr (2012) <doi:10.3102/1076998610396900>, with normally distributed test scores and a binary outcome indicator. A pseudo-likelihood approach, Wolfinger (1993) <doi:10.1080/00949659308811554>, is used for the estimation of this joint generalized linear mixed model. The inner loop of the pseudo-likelihood routine (estimation of a linear mixed model) occurs in the framework of the EM algorithm presented by Karl, Yang, and Lohr (2013) <DOI:10.1016/j.csda.2012.10.004>. This material is based upon work supported by the National Science Foundation under grants DRL-1336027 and DRL-1336265. / GPL-2	linux-64, osx-64, win-64
r-reams	0.1	Resampling methods for adaptive linear model selection. These can be thought of as extensions of the Akaike information criterion that account for searching among candidate models. / GPL-2	noarch
r-rearrangement	2.1	The rearrangement operator (Hardy, Littlewood, and Polya 1952) for univariate, bivariate, and trivariate point estimates of monotonic functions. The package additionally provides a function that creates simultaneous confidence intervals for univariate functions and applies the rearrangement operator to these confidence intervals. / GPL-2	noarch
r-reat	3.0.1	Collection of models and analysis methods used in regional and urban economics and (quantitative) economic geography, e.g. measures of inequality, regional disparities and convergence, regional specialization as well as accessibility and spatial interaction models. / GPL-2	noarch
r-rebmix	2.10.3	R functions for random univariate and multivariate finite mixture model generation, estimation, clustering, latent class analysis and classification. Variables can be continuous, discrete, independent or dependent and may follow normal, lognormal, Weibull, gamma, binomial, Poisson, Dirac or circular von Mises parametric families. / GPL-2	linux-64, osx-64, win-64
r-rebus.base	0.0.3	Build regular expressions piece by piece using human readable code. This package contains core functionality, and is primarily intended to be used by package developers. / Unlimited	noarch
r-reca	1.7	Relevant Component Analysis (RCA) tries to find a linear transformation of the feature space such that the effect of irrelevant variability is reduced in the transformed space. / GPL-3	noarch
r-rechonest	1.2	The ‘Echo nest’ < http://the.echonest.com > is the industry’s leading music intelligence company, providing developer with deepest understanding of music content and music fans. This package can be used to access artist’s data including songs, blogs, news, reviews etc. Song’s data including audio summary, style, danceability, tempo etc can also be accessed. / MIT	noarch
r-recipe	3.0	Pathways in a database could have many redundancies among them. This package allows the user to set a maximum value for the proportion of these redundancies. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-recipes	0.1.5	An extensible framework to create and preprocess design matrices. Recipes consist of one or more data manipulation and analysis steps. Statistical parameters for the steps can be estimated from an initial data set and then applied to other data sets. The resulting design matrices can then be used as inputs into statistical or machine learning models. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-recoder	0.1	Simple, easy to use, and flexible functionality for recoding variables. It allows for simple piecewise definition of transformations. / GPL-2	noarch
r-recombinator	1.0.1	Turns nested lists into data.frames in an orderly manner. / MIT	noarch
r-recommended	3.6.0	R is a free software environment for statistical computing and graphics. / GPL-3.0	linux-32, linux-64, osx-64, win-32, win-64
r-reconstructr	2.0.2	Functions to reconstruct sessions from web log or other user trace data and calculate various metrics around them, producing tabular, output that is compatible with 'dplyr' or 'data.table' centered processes. / MIT	linux-64, osx-64, win-64
r-recorder	0.8.2	A lightweight toolkit to validate new observations when computing their predictions with a predictive model. The validation process consists of two steps: (1) record relevant statistics and meta data of the variables in the original training data for the predictive model and (2) use these data to run a set of basic validation tests on the new set of observations. / MIT	noarch
r-records	1.0	Functions for generating k-record values and k-record times / GPL-2	noarch
r-recosystem	0.4.2	R wrapper of the 'libmf' library < http://www.csie.ntu.edu.tw/~cjlin/libmf/ > for recommender system using matrix factorization. It is typically used to approximate an incomplete matrix using the product of two matrices in a latent space. Other common names for this task include collaborative filtering, matrix completion, matrix recovery, etc. High performance multi-core parallel computing is supported in this package. / BSD_3_clause	linux-64, osx-64, win-64
r-recurse	1.1.0	Computes revisitation metrics for trajectory data, such as the number of revisitations for each location as well as the time spent for that visit and the time since the previous visit. Also includes functions to plot data. / MIT	linux-64, osx-64, win-64
r-redas	0.9.3	Provides functions used in the 'R: Einführung durch angewandte Statistik' (second edition). / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-redm	0.7.2	A new implementation of EDM algorithms based on research software previously developed for internal use in the Sugihara Lab (UCSD/SIO). Contains C compiled objects that use time delay embedding to perform state-space reconstruction and nonlinear forecasting and an R interface to those objects using 'Rcpp'. It supports both the simplex projection method from Sugihara & May (1990) <DOI:10.1038/344734a0> and the S-map algorithm in Sugihara (1994) <DOI:10.1098/rsta.1994.0106>. In addition, this package implements convergent cross mapping as described in Sugihara et al. (2012) <DOI:10.1126/science.1227079> and multiview embedding as described in Ye & Sugihara (2016) <DOI:10.1126/science.aag0863>. / file LICENSE	linux-64, osx-64, win-64
r-redmonder	0.2.0	Provide color schemes for maps (and other graphics) based on the color palettes of several Microsoft(r) products. Forked from 'RColorBrewer' v1.1-2. / Apache License 2.0	noarch
r-reemtree	0.90.3	This package estimates regression trees with random effects as a way to use data mining techniques to describe longitudinal or panel data. / GPL-3	noarch
r-reffreeewas	2.2	Reference-free method for conducting EWAS while deconvoluting DNA methylation arising as mixtures of cell types. The older method (Houseman et al., 2014, <doi:10.1093/bioinformatics/btu029>) is similar to surrogate variable analysis (SVA and ISVA), except that it makes additional use of a biological mixture assumption. The newer method (Houseman et al., 2016, <doi:10.1186/s12859-016-1140-4>) is similar to non-negative matrix factorization, with additional constraints and additional utilities. / GPL-2	noarch
r-refinr	0.3.1	These functions take a character vector as input, identify and cluster similar values, and then merge clusters together so their values become identical. The functions are an implementation of the key collision and ngram fingerprint algorithms from the open source tool Open Refine < http://openrefine.org/ >. More info on key collision and ngram fingerprint can be found here < https://github.com/OpenRefine/OpenRefine/wiki/Clustering-In-Depth >. / GPL-3	linux-64, osx-64, win-64
r-refmanager	1.2.12	Provides tools for importing and working with bibliographic references. It greatly enhances the 'bibentry' class by providing a class 'BibEntry' which stores 'BibTeX' and 'BibLaTeX' references, supports 'UTF-8' encoding, and can be easily searched by any field, by date ranges, and by various formats for name lists (author by last names, translator by full names, etc.). Entries can be updated, combined, sorted, printed in a number of styles, and exported. 'BibTeX' and 'BibLaTeX' '.bib' files can be read into 'R' and converted to 'BibEntry' objects. Interfaces to 'NCBI Entrez', 'CrossRef', and 'Zotero' are provided for importing references and references can be created from locally stored 'PDF' files using 'Poppler'. Includes functions for citing and generating a bibliography with hyperlinks for documents prepared with 'RMarkdown' or 'RHTML'. / GPL-2 GPL-3 BSD_3_clause	noarch
r-refnr	0.1.0	A tool for refining data frame with formulas. / Apache License 2.0 file LICENSE	noarch
r-refset	0.1.1	Provides subsets with reference semantics, i.e. subsets which automatically reflect changes in the original object, and which optionally update the original object when they are changed. / GPL-2	noarch
r-regclust	1.0	This package clusters regression coefficients using the methods of clustering through linear regression models (CLM) (Qin and Self 2006). Maximum likelihood approach is used to infer the parameters for each cluster. Bayesian information criterion (BIC) combined with Bootstrapped maximum volume (BMV) criterion are used to determine the number of clusters. / Artistic-2.0	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-regent	1.0.6	Produces population distribution of disease risk and statistical risk categories, and predicts risks for individuals with genotype information. / GPL-3	noarch
r-regexpipes	0.0.1	Provides wrappers around base::grep() where the first argument is standardized to take the data object. This makes it less of a pain to use regular expressions with 'magrittr' or other pipe operators. / GPL-2	noarch
r-regexselect	1.0.0	'shiny' extension that adds regular expression filtering capabilities to the choice vector of the select list. / GPL-2 GPL-3	noarch
r-registry	0.5.1	Provides a generic infrastructure for creating and using registries. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-reglogit	1.2.6	Regularized (polychotomous) logistic regression by Gibbs sampling. The package implements subtly different MCMC schemes with varying efficiency depending on the data type (binary v. binomial, say) and the desired estimator (regularized maximum likelihood, or Bayesian maximum a posteriori/posterior mean, etc.) through a unified interface. / LGPL-3	linux-64, osx-64, win-64
r-regnet	0.4.0	Network-based regularization has achieved success in variable selection for high-dimensional biological data due to its ability to incorporate correlations among genomic features. This package provides procedures of network-based variable selection for generalized linear models (Ren et al. (2017) <doi:10.1186/s12863-017-0495-5> and Ren et al. (2019) <doi:10.1002/gepi.22194>). Two recent additions are the robust network regularization for the survival response and the network regularization for continuous response. Functions for other regularization methods will be included in the forthcoming upgraded versions. / GPL-2	linux-64, osx-64, win-64
r-regpro	0.1.1	Tools are provided for (1) nonparametric regression (kernel, local linear), (2) semiparametric regression (single index, additive models), and (3) quantile regression (linear, kernel). / GPL-2	noarch
r-regress	1.3.1	Functions to fit Gaussian linear model by maximising the residual log likelihood where the covariance structure can be written as a linear combination of known matrices. Can be used for multivariate models and random effects models. Easy straight forward manner to specify random effects models, including random interactions. Code now optimised to use Sherman Morrison Woodbury identities for matrix inversion in random effects models. We've added the ability to fit models using any kernel as well as a function to return the mean and covariance of random effects conditional on the data (BLUPs). / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-regressionfactory	0.7.2	The expander functions rely on the mathematics developed for the Hessian-definiteness invariance theorem for linear projection transformations of variables, described in authors' paper, to generate the full, high-dimensional gradient and Hessian from the lower-dimensional derivative objects. This greatly relieves the computational burden of generating the regression-function derivatives, which in turn can be fed into any optimization routine that utilizes such derivatives. The theorem guarantees that Hessian definiteness is preserved, meaning that reasoning about this property can be performed in the low-dimensional space of the base distribution. This is often a much easier task than its equivalent in the full, high-dimensional space. Definiteness of Hessian can be useful in selecting optimization/sampling algorithms such as Newton-Raphson optimization or its sampling equivalent, the Stochastic Newton Sampler. Finally, in addition to being a computational tool, the regression expansion framework is of conceptual value by offering new opportunities to generate novel regression problems. / GPL-2	noarch
r-regsel	0.2	Functions for fitting linear and generalized linear models with variable selection. The functions can automatically do Stepwise Regression, Lasso or Elastic Net as variable selection methods. Lasso and Elastic net are improved and handle factors better (they can either include or exclude all factor levels). / GPL-2	noarch
r-regspec	2.4	Computes linear Bayesian spectral estimates from multirate data for second-order stationary time series. Provides credible intervals and methods for plotting various spectral estimates. / GPL-2	noarch
r-regsubseq	0.12	For a sequence of event occurrence times, we are interested in finding subsequences in it that are too regular. We define regular as being significantly different from a homogeneous Poisson process. The departure from the Poisson process is measured using a L1 distance. See Di and Perlman 2007 for more details. / GPL-2	noarch
r-regtest	0.05	Functions for unary and binary regression tests / file LICENSE (Restricts use)	noarch
r-rehh.data	1.0.0	Contains example data for the 'rehh' package. / GPL-2	noarch
r-reinforcelearn	0.2.1	Implements reinforcement learning environments and algorithms as described in Sutton & Barto (1998, ISBN:0262193981). The Q-Learning algorithm can be used with function approximation, eligibility traces (Singh & Sutton (1996) <doi:10.1007/BF00114726>) and experience replay (Mnih et al. (2013) <arXiv:1312.5602>). / MIT	noarch
r-reins	1.0.8	Functions from the book Reinsurance: Actuarial and Statistical Aspects (2017) by Hansjoerg Albrecher, Jan Beirlant and Jef Teugels < http://www.wiley.com/WileyCDA/WileyTitle/productCd-0470772689.html >. / GPL-2	linux-64, osx-64, win-64
r-reinstallr	0.1.4	Search R files for not installed packages and run install.packages. / GPL-3	noarch
r-rel	1.3.1	Derives point estimates with confidence intervals for Bennett et al's S, Cohen's kappa, Conger's kappa, Fleiss' kappa, Gwet's AC, intraclass correlation coefficients, Krippendorff's alpha, Scott's pi, the standard error of measurement, and weighted kappa. / GPL-3	noarch
r-rela	4.1	Item analysis with alpha standard error and principal axis factoring for continuous variable scales (with plots). / Artistic-2.0	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-relabelloadings	1.0	In confirmatory factor analysis (CFA), structural constraints typically ensure that the model is identified up to all possible reflections, i.e., column sign changes of the matrix of loadings. Such reflection invariance is problematic for Bayesian CFA when the reflection modes are not well separated in the posterior distribution. Imposing rotational constraints – fixing some loadings to be zero or positive in order to pick a factor solution that corresponds to one reflection mode – may not provide a satisfactory solution for Bayesian CFA. The function ‘relabel’ uses the relabeling algorithm of Erosheva and Curtis to correct for sign invariance in MCMC draws from CFA models. The MCMC draws should come from Bayesian CFA models that are fit without rotational constraints. / GPL-2	noarch
r-relatable	1.0.0	Functions to safely map from a vector of keys to a vector of values, determine properties of a given relation, or ensure a relation conforms to a given type, such as many-to-many, one-to-many, injective, surjective, or bijective. Permits default return values for use similar to a vectorised switch statement, as well as safely handling large vectors, NAs, and duplicate mappings. / MIT	noarch
r-relatedness	2.0	Inference of relatedness coefficients from a bi-allelic genotype matrix using a Maximum Likelihood estimation, Laporte, F., Charcosset, A. and Mary-Huard, T. (2017) <doi:10.1111/biom.12634>. / AGPL-3	linux-64, osx-64, win-64
r-relaxnet	0.3_2	Extends the glmnet package with relaxation, done by running glmnet once on the entire predictor matrix, then again on each different subset of variables from along the regularization path. Relaxation may lead to improved prediction accuracy for truly sparse data generating models, as well as fewer false positives (i.e. fewer noncontributing predictors in the final model). Penalty may be lasso (alpha = 1) or elastic net (0 < alpha < 1). For this version, family may be gaussian or binomial only. Takes advantage of fast FORTRAN code from the glmnet package. / GPL-2	noarch
r-relaxo	0.1_2	Relaxed Lasso is a generalisation of the Lasso shrinkage technique for linear regression. Both variable selection and parameter estimation is achieved by regular Lasso, yet both steps do not necessarily use the same penalty parameter. The results include all standard Lasso solutions but allow often for sparser models while having similar or even slightly better predictive performance if many predictor variables are present. The package depends on the LARS package. / GPL-3	noarch
r-relen	1.0.1	This function computes the relative entropy (H) as an index for qualitative variation of a factor. / GPL-2	noarch
r-reliability	0.0_2	Functions for estimating parameters in software reliability models. Only infinite failure models are implemented so far. / Unlimited	noarch
r-reliar	0.01	A collection of utilities for some reliability models/probability distributions. / GPL-2	noarch
r-relimp	1.0_5	Functions to facilitate inference on the relative importance of predictors in a linear or generalized linear model, and a couple of useful Tcl/Tk widgets. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-relsurv	2.2_3	Contains functions for analysing relative survival data, including nonparametric estimators of net (marginal relative) survival, relative survival ratio, crude mortality, methods for fitting and checking additive and multiplicative regression models, transformation approach, methods for dealing with population mortality tables. / GPL-3	linux-64, osx-64, win-64
r-relvalanalysis	1.0	Classes and functions for analyzing the performance of portfolios relative to a benchmark. / GPL-2 GPL-3	noarch
r-rem	1.3.1	Calculate endogenous network effects in event sequences and fit relational event models (REM): Using network event sequences (where each tie between a sender and a target in a network is time-stamped), REMs can measure how networks form and evolve over time. Endogenous patterns such as popularity effects, inertia, similarities, cycles or triads can be calculated and analyzed over time. / GPL-2	linux-64, osx-64, win-64
r-rematch	1.0.1	A small wrapper on ‘regexr’ to extract the matches and captured groups from the match of a regular expression to a character vector. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rematch2	2.1.0	Wrappers on ‘regexr’ and ‘gregexpr’ to return the match results in tidy data frames. / MIT	noarch
r-remindr	0.0.1	Insert/extract text reminders into/from function source code comments or as the comment attribute of any object. The former can be handy in development as reminders of e.g. argument requirements, expected objects in the calling environment, required options settings, etc. The latter can be used to provide information of the object and as simple manual tooltips for users, among other things. / GPL-2 GPL-3	noarch
r-remmap	0.2_0	remMap is developed for fitting multivariate response regression models under the high-dimension-low-sample-size setting / GPL-2	linux-64, osx-64, win-64
r-remotes	2.0.4	Download and install R packages stored in ‘GitHub’, ‘BitBucket’, or plain ‘subversion’ or ‘git’ repositories. This package provides the ‘install_*’ functions in ‘devtools’. Indeed most of the code was copied over from ‘devtools’. / GPL (>= 2)	noarch
r-renpow	0.1_1	Supports calculations and visualization for renewable power systems and the environment. Analysis and graphical tools for DC and AC circuits and their use in electric power systems. Analysis and graphical tools for thermodynamic cycles and heat engines, supporting efficiency calculations in coal-fired power plants, gas-fired power plants. Calculations of carbon emissions and atmospheric CO2 dynamics. Analysis of power flow and demand for the grid, as well as power models for microgrids and off-grid systems. Provides resource and power generation for hydro power, wind power, and solar power. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rentrez	1.2.2	Provides an R interface to the NCBI's 'EUtils' API, allowing users to search databases like 'GenBank' < https://www.ncbi.nlm.nih.gov/genbank/ > and 'PubMed' < https://www.ncbi.nlm.nih.gov/pubmed/ >, process the results of those searches and pull data into their R sessions. / MIT	noarch
r-reordercluster	1.0	Tools for performing the leaf reordering for the dendrogram that preserves the hierarchical clustering result and at the same time tries to group instances from the same class together. / GPL-3	linux-64, osx-64, win-64
r-repeatedhighdim	2.0.0	Global tests for expression data of high-dimensional sets of molecular features. / GPL-2	noarch
r-repec	0.1.0	Utilities for accessing RePEc (Research Papers in Economics) through a RESTful API. You can request a code and get detailed information at the following page: < https://ideas.repec.org/api.html >. / MIT	noarch
r-repfd	1.2.3	Estimation of Bayes and local Bayes false discovery rates for replicability analysis (Heller & Yekutieli, 2014 <doi:10.1214/13-AOAS697> ; Heller et al., 2015 <doi: 10.1093/bioinformatics/btu434>). / GPL-2	linux-64, osx-64, win-64
r-repo	2.1.3	A data manager meant to avoid manual storage/retrieval of data to/from the file system. It builds one (or more) centralized repository where R objects are stored with rich annotations, including corresponding code chunks, and easily searched and retrieved. / GPL-3	noarch
r-repogenerator	0.0.1	Generates a project and repo for easy initialization of a GitHub repo for R workshops. The repo includes a README with instructions to ensure that all users have the needed packages, an 'RStudio' project with the right directories and the proper data. The repo can then be used for hosting code taught during the workshop. / MIT	noarch
r-repolr	3.4	Fits linear models to repeated ordinal scores using GEE methodology. / GPL-3	linux-64, osx-64, win-64
r-reportreg	0.3.0	Provides an easy way to report the results of regression analysis, including: 1. Proportional hazards regression from function 'coxph' of package 'survival'; 2. Conditional logistic regression from function 'clogit' of package 'survival'; 3. Ordered logistic regression from function 'polr' of package 'MASS'; 4. Binary logistic regression from function 'glm' of package 'stats'; 5. Linear regression from function 'lm' of package 'stats'; 6. Risk regression model for survival analysis with competing risks from function 'FGR' of package 'riskRegression'; 7. Multilevel model from function 'lme' of package 'nlme'. / GPL-3	noarch
r-reportroc	3.4	Provides an easy way to report the results of ROC analysis, including: 1. an ROC curve. 2. the value of Cutoff, AUC (Area Under Curve), ACC (accuracy), SEN (sensitivity), SPE (specificity), PLR (positive likelihood ratio), NLR (negative likelihood ratio), PPV (positive predictive value), NPV (negative predictive value). / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-reports	0.1.4	Assists in writing reports and presentations by providing a frame work that brings together existing R, LaTeX/docx and Pandoc tools. The package is designed to be used with RStudio, MiKTeX/Tex Live/LibreOffice, knitr, knitrations, Pandoc and pander. The user will want to download these free programs/packages to maximize the effectiveness of the reports package. Functions with two letter names are general text formatting functions for copying text from articles for inclusion as a citation. / GPL-2	noarch
r-reporttools	1.1.2	These functions are especially helpful when writing reports of data analysis using Sweave. / GPL-2	noarch
r-repr	0.19.2	String and binary representations of objects for several formats / mime types. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-represent	1.0	Contains workhorse function jrparams(), as well as two helper functions Mboxtest() and JRsMahaldist(), and four example data sets. / GPL-3	noarch
r-repretools	0.1.2	Reproducible research tools automates the creation of an analysis directory structure and work flow. There are R markdown skeletons which encapsulate typical analytic work flow steps. Functions will create appropriate modules which may pass data from one step to another. / GPL-3	noarch
r-reprex	0.2.1	Convenience wrapper that uses the ‘rmarkdown’ package to render small snippets of code to target formats that include both code and output. The goal is to encourage the sharing of small, reproducible, and runnable examples on code-oriented websites, such as < https://stackoverflow.com > and < https://github.com >, or in email. The user’s clipboard is the default source of input code and the default target for rendered output. ‘reprex’ also extracts clean, runnable R code from various common formats, such as copy/paste from an R session. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-reqs	0.8.1	This package contains the function run.eqs() which calls an EQS script file, executes the EQS estimation, and, finally, imports the results as R objects. These two steps can be performed separately: call.eqs() calls and executes EQS, whereas read.eqs() imports existing EQS outputs as objects into R. It requires EQS 6.2 (build 98 or higher). / GPL-3	noarch
r-request	0.1.0	High level and easy ‘HTTP’ client for ‘R’. Provides functions for building ‘HTTP’ queries, including query parameters, body requests, headers, authentication, and more. / MIT	noarch
r-requirer	1.0.0	Modularizes source code. Keeps the global environment clean, explicifies interdependencies. Inspired by ‘RequireJS’ < http://requirejs.org/ >. / MIT	noarch
r-rerefact	1.0	Executes a post-rotation algorithm that REorders and/or REFlects FACTors (REREFAC) for each replication of a simulation study with exploratory factor analysis. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-resample</code>	0.4	Bootstrap, permutation tests, and other resampling functions, featuring easy-to-use syntax. / BSD_3_clause	noarch
<code>r-resampled</code>	0.3.1	Package of data sets from Mathematical Statistics with Resampling in R (1st Ed. 2011, 2nd Ed. 2018) by Laura Chihara and Tim Hesterberg. / CC0	noarch
<code>r-resemble</code>	1.2.2	Implementation of functions for spectral similarity/dissimilarity analysis and memory-based learning (MBL) for non-linear modeling in complex spectral datasets. In chemometrics MBL is also known as local modeling. / GPL-3	linux-64, osx-64, win-64
<code>r-reservoir</code>	1.1.5	Measure single-storage water supply system performance using resilience, reliability, and vulnerability metrics; assess storage-yield-reliability relationships; determine no-fail storage with sequent peak analysis; optimize release decisions for water supply, hydropower, and multi-objective reservoirs using deterministic and stochastic dynamic programming; generate inflow replicates using parametric and non-parametric models; evaluate inflow persistence using the Hurst coefficient. / GPL-2	noarch
<code>r-reshape</code>	0.8.8	Flexibly restructure and aggregate data using just two functions: melt and cast. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
<code>r-reshape2</code>	1.4.3	Flexibly restructure and aggregate data using just two functions: melt and 'dcast' (or 'acast'). / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
<code>r-resistorarray</code>	1.0.3	Electrical properties of resistor networks using matrix methods. / GPL-2	noarch
<code>r-ress</code>	1.3	Contains three functions that query AuriQ Systems' Essentia Database and return the results in R. 'essQuery' takes a single Essentia command and captures the output in R, where you can save the output to a dataframe or stream it directly into additional analysis. 'read.essentia' takes an Essentia script and captures the output csv data into R, where you can save the output to a dataframe or stream it directly into additional analysis. 'capture.essentia' takes a file containing any number of Essentia commands and captures the output of the specified statements into R dataframes. Essentia can be downloaded for free at http://www.auriq.com/documentation/source/install/index.html . / LGPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-restimizeapi	1.0.0	Provides the user with functions to develop their trading strategy, uncover actionable trading ideas, and monitor consensus shifts with crowdsourced earnings and economic estimate data directly from <www.estimize.com>. Further information regarding the web services this package invokes can be found at <www.estimize.com/api>. / LGPL-3	noarch
r-restorepoint	0.2	Debugging with restore points instead of break points. A restore point stores all local variables when called inside a function. The stored values can later be retrieved and evaluated in a modified R console that replicates the function's environment. To debug step by step, one can simply copy & paste the function body from the R script. Particularly convenient in combination with RStudio. See the Github page inst/vignettes for a tutorial. / GPL-2	noarch
r-restrictedmvn	1.0	A fast Gibbs sampler for multivariate normal with affine constraints. / GPL-2	linux-64, osx-64, win-64
r-rethinker	1.1.0	Simple, native 'RethinkDB' client. / GPL-3	noarch
r-reticulate	1.12	Interface to 'Python' modules, classes, and functions. When calling into 'Python', R data types are automatically converted to their equivalent 'Python' types. When values are returned from 'Python' to R they are converted back to R types. Compatible with all versions of 'Python' >= 2.7. / Apache License 2.0	linux-32, linux-64, osx-64, win-32, win-64
r-retimes	0.1_2	Reaction time analysis by maximum likelihood / GPL-3	linux-64, osx-64, win-64
r-retrodesign	0.1.0	Provides tools for working with Type S (Sign) and Type M (Magnitude) errors, as proposed in Gelman and Tuerlinckx (2000) < doi.org/10.1007/s001800000040 > and Gelman & Carlin (2014) < doi.org/10.1177/1745691614551642 >. In addition to simply calculating the probability of Type S/M error, the package includes functions for calculating these errors across a variety of effect sizes for comparison, and recommended sample size given tolerances for Type S/M errors. To improve the speed of these calculations, closed forms solutions for the probability of a Type S/M error from Lu, Qiu, and Deng (2018) < doi.org/10.1111/bmsp.12132 > are implemented. As of 1.0.0, this includes support only for simple research designs. See the package vignette for a fuller exposition on how Type S/M errors arise in research, and how to analyze them using the type of design analysis proposed in the above papers. / MIT	noarch
r-reval	2.0.0	Simplified scenario testing and sensitivity analysis with R via a generalized function for one-factor-at-a-time (OFAT) sensitivity analysis, evaluation of parameter sets and (sampled) parameter permutations. Options for formatting output and parallel processing are also provided. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-revealjs	0.9	R Markdown format for ‘reveal.js’ presentations, a framework for easily creating beautiful presentations using HTML. / MIT	noarch
r-revecor	0.99.3	An implementation of the reverse ecology framework. Reverse ecology refers to the use of genomics to study ecology with no a priori assumptions about the organism(s) under consideration, linking organisms to their environment. It allows researchers to reconstruct the metabolic networks and study the ecology of poorly characterized microbial species from their genomic information, and has substantial potentials for microbial community ecological analysis. / GPL-2	noarch
r-revgeo	0.15	Function revgeo() allows you to use the Photon geocoder for OpenStreetMap < http://photon.komoot.de >, Google Maps < http://maps.google.com >, and Bing < https://www.bingmapsportal.com > to reverse geocode coordinate pairs with minimal hassle. / GPL (>= 3.0)	noarch
r-revoioq	10.0.0	Test suite for Microsoft R Services. / GPL-2	linux-64, osx-64, win-64
r-revomods	11.0.0	Microsoft modifications and extensions to standard R functions / GPL-2	linux-64, osx-64, win-64
r-revoutils	11.0.0	Utility functions for Microsoft R / GPL-2	linux-64, osx-64, win-64
r-revoutilsmath	11.0.0	Utility functions for managing math threading. / file LICENSE	linux-64, win-64
r-reweight	1.2.1	Adjusts the weights of survey respondents so that the marginal distributions of certain variables fit more closely to those from a more precise source (e.g. Census Bureau’s data). / GPL-2	noarch
r-rex	1.1.2	A friendly interface for the construction of regular expressions. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rexperigen	0.2.1	Provides convenience functions to communicate with an Experigen server: Experigen (http://github.com/aquincum/experigen) is an online framework for creating linguistic experiments, and it stores the results on a dedicated server. This package can be used to retrieve the results from the server, and it is especially helpful with registered experiments, as authentication with the server has to happen. / GPL-3	linux-64, osx-64, win-64
r-rexpokit	0.26.6	Wraps some of the matrix exponentiation utilities from EXPOKIT (http://www.maths.uq.edu.au/expokit/), a FORTRAN library that is widely recommended for matrix exponentiation (Sidje RB, 1998. Expokit: A Software Package for Computing Matrix Exponentials. ACM Trans. Math. Softw. 24(1): 130-156). EXPOKIT includes functions for exponentiating both small, dense matrices, and large, sparse matrices (in sparse matrices, most of the cells have value 0). Rapid matrix exponentiation is useful in phylogenetics when we have a large number of states (as we do when we are inferring the history of transitions between the possible geographic ranges of a species), but is probably useful in other ways as well. / GPL-2	linux-64, osx-64, win-64
r-rfacebook	0.6.15	Provides an interface to the Facebook API. / GPL-2	noarch
r-rfdsn	0.0.0	This package facilitates searching for and downloading seismic time series in miniSEED format (a minimalist version of the Standard for the Exchange of Earthquake Data) from International Federation of Digital Seismograph Networks repositories. This package can also be used to gather information about seismic networks (stations, channels, locations, etc) and find historical earthquake data (origins, magnitudes, etc). / GPL-3	noarch
r-rferns	3.0.0	Provides the random ferns classifier by Ozuysal, Calonder, Lepetit and Fua (2009) <doi:10.1109/TPAMI.2009.23>, modified for generic and multi-label classification and featuring OOB error approximation and importance measure as introduced in Kursu (2014) <doi:10.18637/jss.v061.i10>. / GPL-3	linux-64, osx-64, win-64
r-rfgls	1.1	RFGLS uses a generalized least-squares method to perform single-marker association analysis, in datasets of nuclear families containing parents, twins, and/or adoptees / GPL-2	noarch
r-rfinanceyj	0.3.1	Japanese stock market from Yahoo!-finance-Japan / BSD_3_clause	noarch
r-rfinterval	1.0.0	An integrated package for constructing random forest prediction intervals using a fast implementation package ‘ranger’. This package can apply the following three methods described in Haozhe Zhang, Joshua Zimmerman, Dan Nettleton, and Daniel J. Nordman (2019) <doi:10.1080/00031305.2019.1585288>: the out-of-bag prediction interval, the split conformal method, and the quantile regression forest. / GPL-3	noarch
r-rfit	0.23.0	OR estimation and inference for linear models. Estimation is for general scores and a library of commonly used score functions is included. / GPL-2	linux-64, osx-64, win-64
r-rflights	0.1.10	Query plane tickets, from several airlines, using the ‘Kiwi’ API (similar to ‘Google Flights’). The API is documented at https://docs.kiwi.com/ . / GPL-3	noarch
r-rflptools	1.6	RFLPtools provides functions to analyse DNA fragment samples (i.e. derived from RFLP-analysis) and standalone BLAST report files (i.e. DNA sequence analysis). / LGPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rfml	0.1.0	Functionality required to efficiently use R with MarkLogic NoSQL Database Server, < http://www.marklogic.com/what-is-marklogic/ >. Many basic and complex R operations are pushed down into the database, which removes the main memory boundary of R and allows to make full use of MarkLogic server. In order to use the package you need a MarkLogic Server version 8 or higher. / GPL-3	noarch
r-rfoaas	2.0.0	R access to the ‘FOAAS’ (F... Off As A Service) web service is provided. / GPL-2	noarch
r-rfolding	1.0	The basic algorithm to perform the folding test of unimodality. Given a dataset X (d dimensional, n samples), the test checks whether the distribution of the data are rather unimodal or rather multimodal. This package stems from the following research publication: Siffer Alban, Pierre-Alain Fouque, Alexandre Termier, and Christine Largouët. Are your data gathered? In Proceedings of the 24th ACM SIGKDD International Conference on Knowledge Discovery Data Mining, pp. 2210-2218. ACM, 2018. <doi:10.1145/3219819.3219994>. / GPL-3	noarch
r-rforcecom	1.1	Insert, update, retrieve, delete and bulk operate datasets with a SaaS based CRM Salesforce.com and a PaaS based application platform Force.com from R. / Apache License 2.0	noarch
r-rfordummies	0.1.4	Contains all the code examples in the book R for Dummies (2nd edition) by Andrie de Vries and Joris Meys. You can view the table of contents as well as the sample code for each chapter. / GPL-2 GPL-3	noarch
r-rforensicbatwing	1.3.1	A modified version (with great help from Ian J. Wilson) of Ian J. Wilson’s program BATWING for calculating forensic trace-suspect match probabilities. / GPL-3	linux-64, osx-64, win-64
r-rformatter	0.1.1	The R Formatter formats R source code. It is very much based on formatR, but tries to improve it by heuristics. For example, spaces can be forced around the division operator /. / GPL-3	noarch
r-rfreak	0.3.0	An R interface to a modified version of the Free Evolutionary Algorithm Kit FrEAK. FrEAK is a toolkit written in Java to design and analyze evolutionary algorithms. Both the R interface and an extended version of FrEAK are contained in the RFreak package. For more information on FrEAK see http://sourceforge.net/projects/freak427/ . / GPL-2	noarch
r-rfutilities	2.1.4	Utilities for Random Forest model selection, class balance correction, significance test, cross validation and partial dependency plots. / GPL-3	noarch
r-rga	0.4.2	Provides functions for accessing and retrieving data from the Google Analytics APIs (https://developers.google.com/analytics/). Supports OAuth 2.0 authorization. Package provides access to the Management, Core Reporting, Multi-Channel Funnels Reporting, Real Time Reporting and Metadata APIs. Access to all the Google Analytics accounts which the user has access to. Auto-pagination to return more than 10,000 rows of the results by combining multiple data requests. Also package provides shiny app to explore the core reporting API dimensions and metrics. / GPL-2	noarch
r-rga4gh	0.1.1	An Interface to the GA4GH API that allows users to easily GET responses and POST requests to GA4GH Servers. See < http://ga4gh.org > for more information about the GA4GH project. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rgabriel	0.7	This package was created to analyze multi-level one-way experimental designs. It is designed to handle vectorized observation and factor data where there are unequal sample sizes and population variance homogeneity can not be assumed. To conduct the Gabriel test, create two vectors: one for your observations and one for the factor level of each observation. The function, <code>rgabriel</code> , conduct the test and save the output as a vector to input into the <code>gabriel.plot</code> function, which produces a confidence interval plot for Multiple Comparison. / GPL-2	noarch
r-rgammagamma	1.0.12	This package implements a Gamma convolution model for background correction. / GPL (>= 2.0)	noarch
r-rgb	1.6.1	Classes and methods to efficiently handle (slice, annotate, draw ...) genomic features (such as genes or transcripts), and an interactive interface to browse them. / GPL-3	linux-64, osx-64, win-64
r-rgbm	1.0.8	Provides an implementation of Regularized LS-TreeBoost & LAD-TreeBoost algorithm for Regulatory Network inference from any type of expression data (Microarray/RNA-seq etc). See Mall et al (2017) <doi:10.1101/132670>. / GPL-3	linux-64, osx-64, win-64
r-rgcca	2.1.2	Multiblock data analysis concerns the analysis of several sets of variables (blocks) observed on the same group of individuals. The main aims of the RGCCA package are: (i) to study the relationships between blocks and (ii) to identify subsets of variables of each block which are active in their relationships with the other blocks. / GPL-2	noarch
r-rgdal	1.4.4	Provides bindings to the 'Geospatial' Data Abstraction Library ('GDAL') (>= 1.11.4) and access to projection/transformation operations from the 'PROJ.4' library. The 'GDAL' and 'PROJ.4' libraries are external to the package, and, when installing the package from source, must be correctly installed first. From 'rgdal' 1.4.1, provision is made for 'PROJ6' accommodation, with 'PROJ6' functionality to follow; from 1.4.1 'rgdal' will build and function when 'PROJ' >= 6. Both 'GDAL' raster and 'OGR' vector map data can be imported into R, and 'GDAL' raster data and 'OGR' vector data exported. Use is made of classes defined in the 'sp' package. Windows and Mac Intel OS X binaries (including 'GDAL', 'PROJ.4' and 'Expat') are provided on 'CRAN'. / GPL-2	osx-64, win-64
r-rgdax	1.0.0	Allow access to both public and private end points to Coinbase Pro (erstwhile GDAX) cryptocurrency exchange. For authenticated flow, users must have valid api, secret and passphrase to be able to connect. / MIT	noarch
r-rgeckoboard	0.1.5	Provides an interface to Geckoboard. / MIT	noarch
r-rgen	0.0.1	Provides popular sampling distributions C routines based in armadillo through a header file approach. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rgendata	1.0	The GenDataSample() and GenDataPopulation() functions create, respectively, a sample or population of multivariate nonnormal data using methods described in Ruscio and Kaczetow (2008). Both of these functions call a FactorAnalysis() function to reproduce a correlation matrix. The EFACompData() function allows users to determine how many factors to retain in an exploratory factor analysis of an empirical data set using a method described in Ruscio and Roche (2012). The latter function uses populations of comparison data created by calling the GenDataPopulation() function. <DOI: 10.1080/00273170802285693>. <DOI: 10.1037/a0025697>. / MIT	noarch
r-rgenetics	0.1	R packages for genetics research / GPL-2	noarch
r-rgenoud	5.8_3	A genetic algorithm plus derivative optimizer. / GPL-3	linux-64, osx-64, win-64
r-rgeode	0.1.0	Provides the hybrid Bayesian method Geometric Density Estimation. On the one hand, it scales the dimension of our data, on the other it performs inference. The method is fully described in the paper Scalable Geometric Density Estimation by Y. Wang, A. Canale, D. Dunson (2016) < http://proceedings.mlr.press/v51/wang16e.pdf >. / GPL-2	linux-64, osx-64, win-64
r-rgeos	0.5_1	Interface to Geometry Engine - Open Source ('GEOS') using the C 'API' for topology operations on geometries. The 'GEOS' library is external to the package, and, when installing the package from source, must be correctly installed first. Windows and Mac Intel OS X binaries are provided on 'CRAN'. ('rgeos' >= 0.5-1): Up to and including 'GEOS' 3.7.1, topological operations succeeded with some invalid geometries for which the same operations fail from and including 'GEOS' 3.7.2. The 'checkValidity=' argument defaults and structure have been changed, from default FALSE to integer default '0L' for 'GEOS' < 3.7.2 (no check), '1L' 'GEOS' >= 3.7.2 (check and warn). A value of '2L' is also provided that may be used, assigned globally using 'set_RGEOS_CheckValidity(2L)', or locally using the 'checkValidity=2L' argument, to attempt zero-width buffer repair if invalid geometries are found. The previous default (FALSE, now '0L') is fastest and used for 'GEOS' < 3.7.2, but will not warn users of possible problems before the failure of topological operations that previously succeeded. / GPL-2	linux-64, osx-64, win-64
r-rgexf	0.15.3	Create, read and write GEXF (Graph Exchange XML Format) graph files (used in Gephi and others). Using the XML package, it allows the user to easily build/read graph files including attributes, GEXF viz attributes (such as color, size, and position), network dynamics (for both edges and nodes) and edge weighting. Users can build/handle graphs element-by-element or massively through data-frames, visualize the graph on a web browser through sigma.js (a javascript library) and interact with the igraph package. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
r-rgf	1.0.6	Regularized Greedy Forest wrapper of the 'Regularized Greedy Forest' < https://github.com/RGF-team/rgf/tree/master/python-package > 'python' package, which also includes a Multi-core implementation (FastRGF) < https://github.com/RGF-team/rgf/tree/master/FastRGF >. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rgift	0.1.5	This package provides some functions to create quizzes in the GIFT format. This format is used by several Virtual Learning Environments such as Moodle. / GPL-2	noarch
r-rgl	0.100.19	Provides medium to high level functions for 3D interactive graphics, including functions modelled on base graphics (plot3d(), etc.) as well as functions for constructing representations of geometric objects (cube3d(), etc.). Output may be on screen using OpenGL, or to various standard 3D file formats including WebGL, PLY, OBJ, STL as well as 2D image formats, including PNG, Postscript, SVG, PGF. / GPL	linux-32, linux-64, osx-64, win-32, win-64
r-rglobi	0.2.19	A programmatic interface to the web service methods provided by Global Biotic Interactions (GloBI). GloBI provides access to spatial-temporal species interaction records from sources all over the world. rglobi provides methods to search species interactions by location, interaction type, and taxonomic name. In addition, it supports Cypher, a graph query language, to allow for executing custom queries on the GloBI aggregate species interaction data set. / MIT	noarch
r-rglwidget	0.2.1	The contents of this package have been merged into rgl, so it is no longer needed. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rgooddata	0.1.1	Export raw reports from 'GoodData' business intelligence platform (see < http://www.gooddata.com > for more information). / GPL-3	noarch
r-rgoogleanalytics	0.1.6	Provides functions for accessing and retrieving data from the Google Analytics API. / Apache License 2.0	noarch
r-rgoogleanalyticspremium	0.1.1	It fires a query to the API to get the unsampled data in R for Google Analytics Premium Accounts. It retrieves data from the Google drive document and stores it into the local drive. The path to the excel file is returned by this package. The user can read data from the excel file into R using read.csv() function. / Apache License 2.0	noarch
r-rgooglefit	0.3.1	Provides interface to Google Fit REST API v1 (see < https://developers.google.com/fit/rest/v1/reference/ >). / MIT	noarch
r-rgooglemaps	1.4.4	Serves two purposes: (i) Provide a comfortable R interface to query the Google server for static maps, and (ii) Use the map as a background image to overlay plots within R. This requires proper coordinate scaling. / GPL-3	noarch
r-rgoogleslides	0.3.1	Previously, when one is working with in the Google Ecosystem (Using Google Drive etc), there is hardly any good workflow of getting the values calculated from R and getting that into Google Slides. The normal and easy way out would be to just copy your work over but when you have a number of analysis to present with a lot of changes between each environment, it just becomes quite cumbersome. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-gr	1.1.15	Geological Survey of Canada (GSC) functions for exploratory data analysis with applied geochemical data, with special application to the estimation of background ranges and identification of outliers, ‘anomalies’, to support mineral exploration and environmental studies. Additional functions are provided to support analytical data QA/QC, ANOVA for investigations of field sampling and analytical variability, and utility tasks. NOTE: function caplot() for concentration-area plots employs package ‘akima’, however, ‘akima’ is only licensed for not-for-profit use. Therefore, not-for-profit users of ‘rgr’ will have to independently make package ‘akima’ available through library(...); and use of function caplot() by for-profit users will fail. / GPL-2	noarch
r-grass7	0.2.1	Interpreted interface between ‘GRASS’ 7 geographical information system and R, based on starting R from within the ‘GRASS’ ‘GIS’ environment, or running free-standing R in a temporary ‘GRASS’ location; the package provides facilities for using all ‘GRASS’ commands from the R command line. This package may not be used for ‘GRASS’ 6, for which ‘spgrass6’ should be used. / GPL-2	noarch
r-groovy	1.3	Integrates the Groovy scripting language with the R Project for Statistical Computing. / LGPL-3	noarch
r-gw	0.1.0	Implementation of the affine-invariant method of Goodman & Weare (2010) <DOI:10.2140/camcos.2010.5.65>, a method of producing Monte-Carlo samples from a target distribution. / MIT	noarch
r-h2	0.2.4	DBI/RJDBC interface to h2 database. h2 version 1.3.175 is included. / Mozilla Public License 1.1	noarch
r-handsontable	0.3.7	An R interface to the ‘Handsontable’ JavaScript library, which is a minimalist Excel-like data grid editor. See < https://handsontable.com/ > for details. / MIT	noarch
r-healthdatagov	1.0.1	An R interface for the HealthData.gov data API. For each data resource, you can filter results (server-side) to select subsets of data. / GPL-2	noarch
r-hive	2.0.0	RHive is an R extension facilitating distributed computing via HIVE query. It provides an easy to use HQL like SQL and R objects and functions in HQL. / Apache License (== 2.0)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-hli	0.0.2	Complete access from ‘R’ to the FIS ‘MarketMap C-Toolkit’ (‘FAME C-HLI’). ‘FAME’ is a fully integrated software and database management system from FIS that provides the following capabilities: Time series and cross-sectional data management; Financial calculation, data analysis, econometrics, and forecasting; Table generation and detailed multicolor, presentation-quality report writing; Multicolor, presentation-quality graphics; What-if analysis; Application development and structured programming; Data transfer to and from other applications; Tools for building customized graphical user interfaces. / AGPL-3	linux-64, osx-64, win-64
r-hmc	1.0.0	Implements simple Hamiltonian Monte Carlo routines in R for sampling from any desired target distribution which is continuous and smooth. See Neal (2017) <arXiv:1701.02434> for further details on Hamiltonian Monte Carlo. Automatic parameter selection is not supported. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rhnerm	1.1	Performs the random heteroscedastic nested error regression model described in Kubokawa, Sugawara, Ghosh and Chaudhuri (2016) <doi:10.5705/ss.202014.0070>. / GPL-2	noarch
r-rhor	1.2.1	Rho is used to test the generalization of inter rater reliability (IRR) statistics. Calculating rho starts by generating a large number of simulated, fully-coded data sets: a sizable collection of hypothetical populations, all of which have a kappa value below a given threshold – which indicates unacceptable agreement. Then kappa is calculated on a sample from each of those sets in the collection to see if it is equal to or higher than the kappa in then real sample. If less than five percent of the distribution of samples from the simulated data sets is greater than actual observed kappa, the null hypothesis is rejected and one can conclude that if the two raters had coded the rest of the data, we would have acceptable agreement (kappa above the threshold). / GPL-3	noarch
r-rhosp	1.10	Evaluating risk (that a patient arises a side effect) during hospitalization is the main purpose of this package. Several methods (Parametric, non parametric and De Vielder estimation) to estimate the risk constant (R) are implemented in this package. There are also functions to simulate the different models of this issue in order to quantify the previous estimators. It is necessary to read at least the first six pages of the report to understand the topic. / GPL-2	noarch
r-rhpcbenchmark	0.1.0	Microbenchmarks for determining the run time performance of aspects of the R programming environment and packages relevant to high-performance computation. The benchmarks are divided into three categories: dense matrix linear algebra kernels, sparse matrix linear algebra kernels, and machine learning functionality. / Apache License 2.0 file LICENSE	noarch
r-rhpcblasctl	0.18.1	Control the number of threads on 'BLAS' (Aka 'GotoBLAS', 'OpenBLAS', 'ACML', 'BLIS' and 'MKL'). And possible to control the number of threads in 'OpenMP'. Get a number of logical cores and physical cores if feasible. / AGPL-3	linux-64, osx-64, win-64
r-rhpcc	1.0	rHpcc is an R package providing an Interface between R and HPCC.Familiarity with ECL (Enterprise Control Language) is a must to use this package.HPCC is a massive parallel-processing computing platform that solves Big Data problems.ECL is the Enterprise Control Language designed specifically for huge data projects using the HPCC platform.Its extreme scalability comes from a design that allows you to leverage every query you create for re-use in subsequent queries as needed. To do this, ECL takes a dictionary approach to building queries wherein each ECL definition defines an Attribute. Each previously defined Attribute can then be used in succeeding ECL Attribute definitions as the language extends itself as you use it. / GPL-2	noarch
r-rht	1.0	This package offers functions to perform regularized Hotelling's T-square test for pathway or gene set analysis. The package is tailored for but not limited to proteomics data, in which sample sizes are often small, a large proportion of the data are missing and/or correlations may be present. / GPL-3	noarch
r-rhymer	1.0.0	Wrapper for 'Datamuse' API to find rhyming and other associated words. This includes words of similar meaning, spelling, or other related words. Learn more about the 'Datamuse' API here < http://www.datamuse.com/api/ >. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-ri	0.9	This package provides a set of tools for conducting exact or approximate randomization-based inference for experiments of arbitrary design. The primary functionality of the package is in the generation, manipulation and use of permutation matrices implied by given experimental designs. Among other features, the package facilitates estimation of average treatment effects, constant effects variance estimation, randomization inference for significance testing against sharp null hypotheses and visualization of data and results. / GPL-2	noarch
r-ri2by2	1.3	Computes attributable effects based confidence interval, permutation test confidence interval, or asymptotic confidence interval for the the average treatment effect on a binary outcome. / GPL-3	linux-64, osx-64, win-64
r-ridge	2.4	Linear and logistic ridge regression functions. Additionally includes special functions for genome-wide single-nucleotide polymorphism (SNP) data. / GPL-2	linux-64, osx-64, win-64
r-ridgefusion	1.0_3	This package implements ridge fusion methodology for inverse covariance matrix estimation for use in quadratic discriminant analysis. The package also contains function for model based clustering using ridge fusion for inverse matrix estimation, as well as tuning parameter selection functions. We have also implemented QDA using joint inverse covariance estimation. / MIT	noarch
r-ridigbio	0.3.5	An interface to iDigBio's search API that allows downloading specimen records. Searches are returned as a data.frame. Other functions such as the metadata end points return lists of information. iDigBio is a US project focused on digitizing and serving museum specimen collections on the web. See < https://www.idigbio.org > for information on iDigBio. / MIT	noarch
r-ridit	1.1	An extension of the Kruskal-Wallis Test that allow selection of arbitrary reference group. Also provide Mean Ridit for each group. Mean Ridit of a group is an estimate of probability a random observation from that group will be greater than or equal to a random observation from reference group. / GPL-2 GPL-3	noarch
r-ridittools	0.1	Functions to compute ridit scores of vectors, compute mean ridits and their standard errors for vectors compared to a reference vector, as described in Fleiss (1981, ISBN:0-471-06428-9), and compute means/SEs for multiple groups in matrices. Data can be either counts or proportions. Emphasis is on ridit analysis of ordered categorical data such as Likert items and pain-rating scales. / GPL-2 GPL-3 MIT	noarch
r-rifle	1.0	Implements the algorithms for solving sparse generalized eigenvalue problem by Tan, et. al. (2018). Sparse Generalized Eigenvalue Problem: Optimal Statistical Rates via Truncated Rayleigh Flow. To appear in Journal of the Royal Statistical Society: Series B. <arXiv:1604.08697>. / GPL-2	noarch
r-rifs	0.1_5	RIFS package provides functionality for generating & plotting prefractals in R^n with various protofractal sets and partition coefficient for iterative segments / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rimpack	1.0	The metrics() function calculates measures of scholarly impact. These include conventional measures, such as the number of publications and the total citations to all publications, as well as modern and robust metrics based on the vector of citations associated with each publication, such as the h index and many of its variants or rivals. These methods are described in Ruscio et al. (2012) <DOI: 10.1080/15366367.2012.711147>. / MIT	noarch
r-ring	1.0.0	Circular / ring buffers in R and C. There are a couple of different buffers here with different implementations that represent different trade-offs. / MIT	linux-64, osx-64, win-64
r-rinside	0.2.15	C classes to embed R in C applications A C class providing the R interpreter is offered by this package making it easier to have R inside your C application. As R itself is embedded into your application, a shared library build of R is required. This works on Linux, OS X and even on Windows provided you use the same tools used to build R itself. d Numerous examples are provided in the eight subdirectories of the examples/ directory of the installed package: standard, 'mpi' (for parallel computing), 'qt' (showing how to embed 'RInside' inside a Qt GUI application), 'wt' (showing how to build a web-application using the Wt toolkit), 'armadillo' (for 'RInside' use with 'RcppArmadillo') and 'eigen' (for 'RInside' use with 'RcppEigen'). The examples use 'GNUmakefile(s)' with GNU extensions, so a GNU make is required (and will use the 'GNUmakefile' automatically). 'Doxygen'-generated documentation of the C classes is available at the 'RInside' website as well. / GPL-2	linux-64, osx-64, win-64
r-rinsp	1.2.3	Functions to calculate several ecological indices of individual and population niche width (Araujo's E, clustering and pairwise similarity among individuals, IS, Petraitis' W, and Roughgarden's WIC/TNW) to assess individual specialization based on data of resource use. Resource use can be quantified by counts of categories, measures of mass/length or proportions. Monte Carlo resampling procedures are available for hypothesis testing against multinomial null models. / GPL-2	linux-64, osx-64, win-64
r-rintervaltree	0.1.0	This tool can be used to build binary interval trees using real number inputs. The tree supports queries of intervals overlapping a single number or an interval (start, end). Intervals with same bounds but different names are treated as distinct intervals. Insertion of intervals is also allowed. Deletion of intervals is not implemented at this point. See Mark de Berg, Otfried Cheong, Marc van Kreveld, Mark Overmars (2008). Computational Geometry: Algorithms and Applications, for a reference. / GPL-2	noarch
r-rintrojs	0.2.2	A wrapper for the 'Intro.js' library (For more info: < http://www.introjs.com >). This package makes it easy to include step-by-step introductions, and clickable hints in a 'Shiny' application. It supports both static introductions in the UI, and programmatic introductions from the server-side. / AGPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rio	0.5.16	Streamlined data import and export by making assumptions that the user is probably willing to make: ‘import()’ and ‘export()’ determine the data structure from the file extension, reasonable defaults are used for data import and export (e.g., ‘stringsAsFactors=FALSE’), web-based import is natively supported (including from SSL/HTTPS), compressed files can be read directly without explicit decompression, and fast import packages are used where appropriate. An additional convenience function, ‘convert()’, provides a simple method for converting between file types. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rip46	1.0.2	Utility functions and S3 classes for IPv4 and IPv6 addresses, including conversion to and from binary representation. / GPL-3	linux-64, osx-64
r-rising	0.1.0	Fits an Ising model to a binary dataset using L1 regularized logistic regression and extended BIC. Also includes a fast lasso logistic regression function for high-dimensional problems. Uses the ‘libLBFGS’ optimization library by Naoaki Okazaki. / GPL-2	linux-64, osx-64, win-64
r-risk	1.0	Computes 26 financial risk measures for any continuous distribution. The 26 financial risk measures include value at risk, expected shortfall due to Artzner et al. (1999) <DOI:10.1007/s10957-011-9968-2>, tail conditional median due to Kou et al. (2013) <DOI:10.1287/moor.1120.0577>, expectiles due to Newey and Powell (1987) <DOI:10.2307/1911031>, beyond value at risk due to Longin (2001) <DOI:10.3905/jod.2001.319161>, expected proportional shortfall due to Belzunce et al. (2012) <DOI:10.1016/j.insmatheco.2012.05.003>, elementary risk measure due to Ahmadi-Javid (2012) <DOI:10.1007/s10957-011-9968-2>, omega due to Shadwick and Keating (2002), sortino ratio due to Rollinger and Hoffman (2013), kappa due to Kaplan and Knowles (2004), Wang (1998)’s <DOI:10.1080/10920277.1998.10595708> risk measures, Stone (1973)’s <DOI:10.2307/2978638> risk measures, Luce (1980)’s <DOI:10.1007/BF00135033> risk measures, Sarin (1987)’s <DOI:10.1007/BF00126387> risk measures, Bronshtein and Kurelenkova (2009)’s risk measures. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-riskparityportfolio	0.2.0	Fast design of risk parity portfolios for financial investment. The goal of the risk parity portfolio formulation is to equalize or distribute the risk contributions of the different assets, which is missing if we simply consider the overall volatility of the portfolio as in the mean-variance Markowitz portfolio. In addition to the vanilla formulation, where the risk contributions are perfectly equalized subject to no shortselling and budget constraints, many other formulations are considered that allow for box constraints and shortselling, as well as the inclusion of additional objectives like the expected return and overall variance. See vignette for a detailed documentation and comparison, with several illustrative examples. The package is based on the papers: Y. Feng, and D. P. Palomar (2015). SCRIP: Successive Convex Optimization Methods for Risk Parity Portfolio Design. IEEE Trans. on Signal Processing, vol. 63, no. 19, pp. 5285-5300. <doi:10.1109/TSP.2015.2452219>. F. Spinu (2013), An Algorithm for Computing Risk Parity Weights. <doi:10.2139/ssrn.2297383>. T. Griveau-Billion, J. Richard, and T. Roncalli (2013). A fast algorithm for computing High-dimensional risk parity portfolios. <arXiv:1311.4057>. / GPL-3	linux-64, osx-64, win-64
r-riskportfolios	2.1.2	Collection of functions designed to compute risk-based portfolios as described in Ardia et al. (2017) <doi:10.1007/s10479-017-2474-7> and Ardia et al. (2017) <doi:10.21105/joss.00171>. / GPL-2	noarch
r-riskr	1.1	Computes risk measures from data, as well as performs risk management procedures. / GPL-2	noarch
r-risksetroc	1.0.4	Compute time-dependent Incident/dynamic accuracy measures (ROC curve, AUC, integrated AUC)from censored survival data under proportional or non-proportional hazard assumption of Heagerty & Zheng (Biometrics, Vol 61 No 1, 2005, PP 92-105). / GPL-2	noarch
r-riskyr	0.2.0	Risk-related information (like the prevalence of conditions and the sensitivity and specificity of diagnostic tests or treatment decisions) can be expressed in terms of probabilities or frequencies. By providing a toolbox of methods and metrics, 'riskyr' computes, translates, and visualizes risk-related information in a variety of ways. Offering multiple complementary perspectives on the interplay between key parameters renders teaching and training of risk literacy more transparent. / GPL-2 GPL-3	noarch
r-rismed	2.1.7	A set of tools to extract bibliographic content from the National Center for Biotechnology Information (NCBI) databases, including PubMed. The name RISmed is a portmanteau of RIS (for Research Information Systems, a common tag format for bibliographic data) and PubMed. / GPL-2	noarch
r-riverbuilder	0.1.1	Generates graphs, CSV files, and coordinates related to river valleys when calling the riverbuilder() function. / GPL-3	noarch
r-riverload	1.0.1	Implements several of the most popular load estimation procedures, including averaging methods, ratio estimators and regression methods. The package provides an easy-to-use tool to rapidly calculate the load for various compounds and to compare different methods. The package also supplies additional functions to easily organize and analyze the data. / GPL-2	noarch
r-rivernet	1.2	Functions for reading, analysing and plotting river networks. For this package, river networks consist of sections and nodes with associated attributes, e.g. to characterise their morphological, chemical and biological state. The package provides functions to read this data from text files, to analyse the network structure and network paths and regions consisting of sections and nodes that fulfill prescribed criteria, and to plot the river network and associated properties. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-riverplot</code>	0.6	Sankey plots are a type of diagram that is convenient to illustrate how flow of information, resources etc. separates and joins, much like observing how rivers split and merge. For example, they can be used to compare different clusterings. / GPL (≥ 2.0)	noarch
<code>r-rivervis</code>	0.46.0	This R package is a flexible and efficient tool to visualise both quantitative and qualitative data from river surveys. It can be used to produce diagrams with the topological structure of the river network. / GPL-2	noarch
<code>r-rivr</code>	1.2.1	A tool for undergraduate and graduate courses in open-channel hydraulics. Provides functions for computing normal and critical depths, steady-state water surface profiles (e.g. backwater curves) and unsteady flow computations (e.g. flood wave routing). / GPL-3	linux-64, osx-64, win-64
<code>r-rjacgh</code>	2.0.4	Bayesian analysis of CGH microarrays fitting Hidden Markov Chain models. The selection of the number of states is made via their posterior probability computed by Reversible Jump Markov Chain Monte Carlo Methods. Also returns probabilistic common regions for gains/losses. / GPL-3	linux-64, osx-64, win-64
<code>r-rjava</code>	0.9.1	Low-level interface to Java VM very much like .C/.Call and friends. Allows creation of objects, calling methods and accessing fields. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
<code>r-rjazz</code>	0.1.7	This is the official ‘Jazz’ client. ‘Jazz’ is a lightweight modular data processing framework, including a web server. It provides data persistence and computation capabilities accessible from ‘R’ and ‘Python’ and also through a REST API. < https://github.com/bbvadata/Jazz > See ?rjazz::rjazz to get a ‘Jazz’ server. / Apache License ($= 2.0$)	noarch
<code>r-rjdbc</code>	0.2.7	The RJDBC package is an implementation of R’s DBI interface using JDBC as a back-end. This allows R to connect to any DBMS that has a JDBC driver. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-rjdemetra</code>	0.1.3	Interface around ‘JDemetra’ (< https://github.com/jdemetra/jdemetra-app >), the seasonal adjustment software officially recommended to the members of the European Statistical System (ESS) and the European System of Central Banks. It offers full access to all options and outputs of ‘JDemetra’, including the two leading seasonal adjustment methods TRAMO/SEATS and X-12ARIMA/X-13ARIMA-SEATS. / EUPL	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rje	1.10.1	A series of functions in some way considered useful to the author. These include functions for subsetting tables and generating indices for arrays, conditioning and intervening in probability distributions, generating combinations and more... / GPL-2	linux-64, osx-64, win-64
r-rjsdmx	2.1.0	Provides functions to retrieve data and metadata from providers that disseminate data by means of SDMX web services. SDMX (Statistical Data and Metadata eXchange) is a standard that has been developed with the aim of simplifying the exchange of statistical information. More about the SDMX standard and the SDMX Web Services can be found at: < http://sdmx.org >. / EUPL	noarch
r-rjson	0.2.20	Converts R object into JSON objects and vice-versa / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-rjsonio	1.3.1	This is a package that allows conversion to and from data in Javascript object notation (JSON) format. This allows R objects to be inserted into Javascript/ECMAScript/ActionScript code and allows R programmers to read and convert JSON content to R objects. This is an alternative to rjson package. Originally, that was too slow for converting large R objects to JSON and was not extensible. rjson's performance is now similar to this package, and perhaps slightly faster in some cases. This package uses methods and is readily extensible by defining methods for different classes, vectorized operations, and C code and callbacks to R functions for deserializing JSON objects to R. The two packages intentionally share the same basic interface. This package (RJSONIO) has many additional options to allow customizing the generation and processing of JSON content. This package uses libjson rather than implementing yet another JSON parser. The aim is to support other general projects by building on their work, providing feedback and benefit from their ongoing development. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-rjsplot	2.5	Creates interactive graphs with 'R'. It joins the data analysis power of R and the visualization libraries of JavaScript in one package. / CC BY-NC-SA 4.0	noarch
r-rjstat	0.3.0	Read and write the 'JSON-stat' format (http://json-stat.org) to and from (lists of) R data frames. Not all features are supported, especially the extensive metadata features of 'JSON-stat'. / MIT	noarch
r-rjwsacruncher	0.1.0	'JDemetra' (< https://github.com/jdemetra/jdemetra-app >) is the seasonal adjustment software officially recommended to the members of the European Statistical System and the European System of Central Banks. Seasonal adjustment models performed with 'JDemetra' can be stored into workspaces. 'JWSACruncher' (< https://github.com/jdemetra/jwsacruncher/releases >) is a console tool that re-estimates all the multi-processing defined in a workspace and to export the result. 'rjwsacruncher' allows to launch easily the 'JWSACruncher'. / GPL-3	noarch
r-rjython	0.0.4	R interface to Python via Jython allowing R to call python code. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rkeajars	5.0_3	External jars required for package RKEA. / GPL-2	noarch
r-rkeedata	1.0.5	'KEEL' is a popular Java software for a large number of different knowledge data discovery tasks. Furthermore, 'RKEEL' is a package with a R code layer between R and 'KEEL', for using 'KEEL' in R code. This package includes the datasets from 'KEEL' in .dat format for its use in 'RKEEL' package. For more information about 'KEEL', see < http://www.keel.es/ >. / GPL-3	noarch
r-rkeeljars	1.0.19	'KEEL' is a popular Java software for a large number of different knowledge data discovery tasks. Furthermore, 'RKEEL' is a package with a R code layer between R and 'KEEL', for using 'KEEL' in R code. This package downloads and install the .jar files necessary for 'RKEEL' algorithms execution. For more information about 'KEEL', see < http://www.keel.es/ >. / GPL-3	noarch
r-rkelly	1.0	Calculates the Kelly criterion (Kelly, J.L. (1956) <doi:10.1002/j.1538-7305.1956.tb03809.x>) for bets given quoted prices, model predictions and commissions. Additionally it contains helper functions to calculate the probabilities for wins and draws in multi-leg games. / MIT	noarch
r-rklout	1.0	An interface of R to Klout API v2. It fetches Klout Score for a Twitter Username/handle in real time. Klout is a website and mobile app that uses social media analytics to rank its users according to online social influence via the Klout Score, which is a numerical value between 1 and 100. In determining the user score, Klout measures the size of a user's social media network and correlates the content created to measure how other users interact with that content. / GPL-2	noarch
r-rkmetrics	1.3	Hybrid Mortality Modelling (HMM) provides a framework in which mortality around the accident hump and at very old ages can be modelled under a single model. The graphics' codes necessary for visualization of the models' output are included here. Specifically, the graphics are based on the assumption that, the mortality rates can be expressed as a function of the area under the curve between the crude mortality rates plots and the tangential transform of the force of mortality. / GPL-3	noarch
r-rknn	1.2_1	Random knn classification and regression are implemented. Random knn based feature selection methods are also included. The approaches are mainly developed for high-dimensional data with small sample size. / GPL-2	linux-64, osx-64, win-64
r-rkt	1.5	Contains function rkt which computes the Mann-Kendall test (MK) and the Seasonal and the Regional Kendall Tests for trend (SKT and RKT) and Theil-Sen's slope estimator. / GPL-2	noarch
r-rkum	0.1.1	Robust kernel center matrix, robust kernel cross-covariance operator for kernel unsupervised methods, kernel canonical correlation analysis, influence function of identifying significant outliers or atypical objects from multimodal datasets. Alam, M. A, Fukumizu, K., Wang Y.-P. (2018) <doi:10.1016/j.neucom.2018.04.008>. Alam, M. A, Calhoun, C. D., Wang Y.-P. (2018) <doi:10.1016/j.csda.2018.03.013>. / GPL-3	noarch
r-rkvo	0.1	This package provides functionality to read files containing observations which consist of arbitrary key/value pairs. / GPL-3	linux-64, osx-64, win-64
r-rlab	2.15.1	Functions and Datasets Required for ST370 class / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rlabkey	2.3.1	The ‘LabKey’ client library for R makes it easy for R users to load live data from a ‘LabKey’ Server, < http://www.labkey.com/ >, into the R environment for analysis, provided users have permissions to read the data. It also enables R users to insert, update, and delete records stored on a ‘LabKey’ Server, provided they have appropriate permissions to do so. / Apache License 2.0	linux-64, osx-64, win-64
r-rlakeanalyzer	1.11.4	Standardized methods for calculating common important derived physical features of lakes including water density based on temperature, thermal layers, thermocline depth, lake number, Wedderburn number, Schmidt stability and others. / GPL-2	noarch
r-rlang	0.3.4	A toolbox for working with base types, core R features like the condition system, and core ‘Tidyverse’ features like tidy evaluation. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-rlas	1.3.3	Read and write ‘las’ and ‘laz’ binary file formats. The LAS file format is a public file format for the interchange of 3-dimensional point cloud data between data users. The LAS specifications are approved by the American Society for Photogrammetry and Remote Sensing < https://www.asprs.org/committee-general/laser-las-file-format-exchange-activities.html >. The LAZ file format is an open and lossless compression scheme for binary LAS format versions 1.0 to 1.3 < https://www.laszip.org/ >. / GPL-3	linux-64, osx-64, win-64
r-rld	1.0	Analyzes data from repeated low-dose challenge experiments and provide vaccine efficacy estimates. In addition, this package can provide guidance to design repeated low-dose challenge studies. / GPL-2	noarch
r-rlda	0.2.6	Estimates the Bayesian LDA model for mixed-membership clustering based on different types of data (i.e., Multinomial, Bernoulli, and Binomial entries). Albuquerque, Valle and Li (2019) <doi:10.1016/j.knosys.2018.10.024>. / GPL-2	linux-64, osx-64, win-64
r-rldcp	1.0.2	Linguistic Descriptions of Complex Phenomena (LDCP) is an architecture and methodology that allows us to model complex phenomena, interpreting input data, and generating automatic text reports customized to the user needs (see <doi:10.1016/j.ins.2016.11.002> and <doi:10.1007/s00500-016-2430-5>). The proposed package contains a set of methods that facilitates the development of LDCP systems. Its main goal is increasing the visibility and practical use of this research line. / GPL-2	noarch
r-rleafangle	1.0	Leaf angle distribution is described by a number of functions (e.g. ellipsoidal, Beta and rotated ellipsoidal). The parameters of leaf angle distributions functions are estimated through different empirical relationship. This package includes estimations of parameters of different leaf angle distribution function, plots and evaluates leaf angle distribution functions, calculates extinction coefficients given leaf angle distribution. Reference: Wang(2007)<doi:10.1016/j.agrformet.2006.12.003>. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rleafletmap	0.2	Display spatial data with interactive maps powered by the open-source JavaScript library ‘Leaflet’ (see < http://leafletjs.com/ >). Maps can be rendered in a web browser or displayed in the HTML viewer pane of ‘RStudio’. This package is designed to be easy to use and can create complex maps with vector and raster data, web served map tiles and interface elements. / GPL-3	noarch
r-rlecuyer	0.3.4	Provides an interface to the C implementation of the random number generator with multiple independent streams developed by L’Ecuyer et al (2002). The main purpose of this package is to enable the use of this random number generator in parallel R applications. / GPL-2	linux-64, osx-64, win-64
r-rlibeemd	1.4.1	An R interface for libeemd (Luukko, Helske, Räsänen, 2016) <doi:10.1007/s00180-015-0603-9>, a C library of highly efficient parallelizable functions for performing the ensemble empirical mode decomposition (EEMD), its complete variant (CEEMDAN), the regular empirical mode decomposition (EMD), and bivariate EMD (BEMD). Due to the possible portability issues CRAN version no longer supports OpenMP, you can install OpenMP-supported version from GitHub: < https://github.com/helske/Rlibeemd/ >. / GPL-3	linux-64, osx-64, win-64
r-rlinkedin	0.2	A series of functions that allow users to access the ‘LinkedIn’ API to get information about connections, search for people and jobs, share updates with their network, and create group discussions. For more information about using the API please visit < https://developer.linkedin.com/ >. / GPL-2	noarch
r-rlist	0.4.6	Provides a set of functions for data manipulation with list objects, including mapping, filtering, grouping, sorting, updating, searching, and other useful functions. Most functions are designed to be pipeline friendly so that data processing with lists can be chained. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rlm	1.2	Robust fitting of linear model which can take response in matrix form. / GPL-2	linux-64, osx-64, win-64
r-rlmdatadriven	0.3.0	Data driven approach for robust regression estimation in homoscedastic and heteroscedastic context. See Wang et al. (2007), <doi:10.1198/106186007X180156> regarding homoscedastic framework. / GPL (>= 2.0)	noarch
r-rlme	0.5	Estimates robust rank-based fixed effects and predicts robust random effects in two- and three- level random effects nested models. The methodology is described in Bilgic & Susmann (2013) < https://journal.r-project.org/archive/2013/RJ-2013-027/ >. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rlof	1.1.1	R parallel implementation of Local Outlier Factor(LOF) which uses multiple CPUs to significantly speed up the LOF computation for large datasets. (Note: The overall performance depends on the computers especially the number of the cores).It also supports multiple k values to be calculated in parallel, as well as various distance measures in addition to the default Euclidean distance. / GPL-2	linux-64, osx-64, win-64
r-rlrsim	3.1.3	Rapid, simulation-based exact (restricted) likelihood ratio tests for testing the presence of variance components/nonparametric terms for models fit with nlme::lme(), lme4::lmer(), lmeTest::lmer(), gamm4::gamm4(), mgcv::gamm() and SemiPar::spm(). / GPL-3	linux-64, osx-64, win-64
r-rlt	3.2.2	Random forest with a variety of additional features for regression, classification and survival analysis. The features include: parallel computing with OpenMP, embedded model for selecting the splitting variable (based on Zhu, Zeng & Kosorok, 2015), subject weight, variable weight, tracking subjects used in each tree, etc. / GPL-2	linux-64, osx-64, win-64
r-rltp	0.1.4	R interface to the ‘LTP’-Cloud service for Natural Language Processing in Chinese (http://www.ltp-cloud.com/). / LGPL-3	linux-64, osx-64, win-64
r-rm2006	0.1.0	Estimation the conditional covariance matrix using the RiskMetrics 2006 methodology of Zumbach (2007) <doi:10.2139/ssrn.1420185>. / GPL-2	noarch
r-rmaf	3.0.1	Uses refined moving average filter based on the optimal and data-driven moving average lag q or smoothing spline to estimate trend and seasonal components, as well as irregularity (residuals) for univariate time series or data. / GPL-2	noarch
r-rmake	1.1.0	Creates and maintains a build process for complex analytic tasks in R. Package allows to easily generate Makefile for the (GNU) ‘make’ tool, which drives the build process by (in parallel) executing build commands in order to update results accordingly to given dependencies on changed data or updated source files. / GPL (>= 3.0)	noarch
r-rmallow	1.0	An EM algorithm to fit Mallows’ Models to full or partial rankings, with or without ties. / GPL-2	noarch
r-rmalschains	0.2.5	An implementation of an algorithm family for continuous optimization called memetic algorithms with local search chains (MA-LS-Chains). Memetic algorithms are hybridizations of genetic algorithms with local search methods. They are especially suited for continuous optimization. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rmargint	1.0.2	Three robust marginal integration procedures for additive models based on local polynomial kernel smoothers. As a preliminary estimator of the multivariate function for the marginal integration procedure, a first approach uses local constant M-estimators, a second one uses local polynomials of order 1 over all the components of covariates, and the third one uses M-estimators based on local polynomials but only in the direction of interest. For this last approach, estimators of the derivatives of the additive functions can be obtained. All three procedures can compute predictions for points outside the training set if desired. See Boente and Martinez (2017) <doi:10.1007/s11749-016-0508-0> for details. / GPL (>= 3.0)	linux-64, osx-64, win-64
r-rmariadb	1.0.6	Implements a 'DBI'-compliant interface to 'MariaDB' (< https://mariadb.org/ >) and 'MySQL' (< https://www.mysql.com/ >) databases. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-rmarkdown	1.12	Convert R Markdown documents into a variety of formats. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rmatio	0.14.0	Read and write 'Matlab' MAT files from R. The 'rmatio' package supports reading MAT version 4, MAT version 5 and MAT compressed version 5. The 'rmatio' package can write version 5 MAT files and version 5 files with variable compression. / GPL-3	linux-64, osx-64, win-64
r-rmawgen	1.3.3	S3 and S4 functions are implemented for spatial multi-site stochastic generation of daily time series of temperature and precipitation. These tools make use of Vector AutoRegressive models (VARs). The weather generator model is then saved as an object and is calibrated by daily instrumental Gaussianized time series through the 'vars' package tools. Once obtained this model, it can be used for weather generations and be adapted to work with several climatic monthly time series. / GPL-2	noarch
r-rmcorr	0.3.0	Compute the repeated measures correlation, a statistical technique for determining the overall within-individual relationship among paired measures assessed on two or more occasions, first introduced by Bland and Altman (1995). Includes functions for diagnostics, p-value, effect size with confidence interval including optional bootstrapping, as well as graphing. Also includes several example datasets. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rmdfiltr	0.1.0	A collection of ‘Lua’ filters that extend the functionality of R Markdown templates (e.g., count words or post-process ‘pandoc-citeproc’- citations). / MIT	noarch
r-rmdplgr	0.4.0	Formats for R Markdown that undo modifications by ‘pandoc’ and ‘rmarkdown’ to original ‘latex’ templates, such as smaller margins, paragraph spacing, and compact titles. In addition, enhancements such as author blocks with affiliations and headers and footers are introduced. All of this functionality is built around plugins that modify the default ‘pandoc’ template without relying on custom templates. / GPL-3	noarch
r-rmdshower	2.1.1	‘R’ ‘Markdown’ format for ‘shower’ presentations, see < https://github.com/shower/shower >. / MIT	noarch
r-rmea	1.1.0	A suite of tools useful to read, visualize and export bivariate motion energy time-series. Lagged synchrony between subjects can be analyzed through windowed cross-correlation. Surrogate data generation allows an estimation of pseudosynchrony that helps to estimate the effect size of the observed synchronization. Ramseyer & Tschacher (2011) <doi:10.1037/a0023419>. / GPL-3	noarch
r-rmecabko	0.1.6.2	An ‘Rcpp’ interface for Eunjeon project < http://eunjeon.blogspot.com/ >. The ‘mecab-ko’ and ‘mecab-ko-dic’ is based on a C library, and part-of-speech tagging with them is useful when the spacing of source Korean text is not correct. This package provides part-of-speech tagging and tokenization function for Korean text. / GPL-2	win-64
r-rmediation	1.1.4	We provide functions to compute confidence intervals (CIs) for a well-defined nonlinear function of the model parameters (e.g., product of k coefficients) in single-level and multilevel structural equation models. / GPL-2	noarch
r-rmeta	3.0	Functions for simple fixed and random effects meta-analysis for two-sample comparisons and cumulative meta-analyses. Draws standard summary plots, funnel plots, and computes summaries and tests for association and heterogeneity. / GPL-2	noarch
r-rmi	0.1.1	Provides mutual information estimators based on k-nearest neighbor estimators by A. Kraskov, et al. (2004) <doi:10.1103/PhysRevE.69.066138>, S. Gao, et al. (2015) < http://proceedings.mlr.press/v38/gao15.pdf > and local density estimators by W. Gao, et al. (2017) <doi:10.1109/ISIT.2017.8006749>. / GPL-3	linux-64, osx-64, win-64
r-rmio	0.1.2	Provides header files of ‘mio’, a cross-platform C11 header-only library for memory mapped file IO < https://github.com/mandreyel/mio >. / GPL-3	noarch
r-rmisc	1.5	The Rmisc library contains many functions useful for data analysis and utility operations. / GPL-3	noarch
r-rmixmod	2.1.2	Interface of ‘MIXMOD’ software for supervised, unsupervised and semi-supervised classification with mixture modelling. / GPL-3	linux-64, osx-64, win-64
r-rmixpanel	0.7.1	Provides an interface to many endpoints of Mixpanel’s Data Export, Engage and JQL API. The R functions allow for event and profile data export as well as for segmentation, retention, funnel and addiction analysis. Results are always parsed into convenient R objects. Furthermore it is possible to load and update profiles. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rmxtcompio	4.0.1	Mixture Composer < https://github.com/modal-inria/MixtComp > is a project to build mixture models with heterogeneous data sets and partially missing data management. It includes models for real, categorical, counting, functional and ranking data. This package contains the minimal R interface of the C ‘MixtComp’ library. / AGPL-3	linux-64, osx-64, win-64
r-rmkdiscrete	0.1	Sundry discrete probability distributions and helper functions. / GPL-2	linux-64, osx-64, win-64
r-rmoajars	1.0.1	External jars required for package RMOA. RMOA is a framework to build data stream models on top of MOA (Massive Online Analysis - < http://moa.cms.waikato.ac.nz >). The jar files are put in this R package, the modelling logic can be found in the RMOA package. / GPL-3	noarch
r-rmonad	0.5.0	A monadic solution to pipeline analysis. All operations – and the errors, warnings and messages they emit – are merged into a directed graph. Infix binary operators mediate when values are stored, how exceptions are handled, and where pipelines branch and merge. The resulting structure may be queried for debugging or report generation. ‘rmonad’ complements, rather than competes with, non-monadic pipeline packages like ‘magrittr’ or ‘pipeR’. This work is funded by the NSF (award number 1546858). / GPL-3	noarch
r-rmosek	1.3.5	This is a meta-package designed to support the installation of Rmosek (>= 6.0) and bring the optimization facilities of MOSEK (>= 6.0) to the R-language. The interface supports large-scale optimization of many kinds: Mixed-integer and continuous linear, second-order cone, exponential cone and power cone optimization, as well as continuous semidefinite optimization. Rmosek and the R-language are open-source projects. MOSEK is a proprietary product, but unrestricted trial and academic licenses are available. / LGPL-2.1	noarch
r-rmpfr	0.7.2	Arithmetic (via S4 classes and methods) for arbitrary precision floating point numbers, including transcendental (special) functions. To this end, the package interfaces to the ‘LGPL’ licensed ‘MPFR’ (Multiple Precision Floating-Point Reliable) Library which itself is based on the ‘GMP’ (GNU Multiple Precision) Library. / GPL-2	linux-64, osx-64
r-rmpw	0.0.4	We implement causal mediation analysis using the methods proposed by Hong (2010) and Hong, Deutsch & Hill (2015) <doi:10.3102/1076998615583902>. It allows the estimation and hypothesis testing of causal mediation effects through ratio of mediator probability weights (RMPW). This strategy conveniently relaxes the assumption of no treatment-by-mediator interaction while greatly simplifying the outcome model specification without invoking strong distributional assumptions. We also implement a sensitivity analysis by extending the RMPW method to assess potential bias in the presence of omitted pretreatment or posttreatment covariates. The sensitivity analysis strategy was proposed by Hong, Qin, and Yang (2018) <doi:10.3102/1076998617749561>. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-rmr</code>	1.1.0	Analysis of oxygen consumption data generated by Loligo (R) Systems respirometry equipment. The package includes a function for loading data output by Loligo's 'AutoResp' software (<code>get.witrox.data()</code>), functions for calculating metabolic rates over user-specified time intervals, extracting critical points from data using broken stick regressions based on Yeager and Ultsch (<DOI:10.1086/physzool.62.4.30157935>), and easy functions for converting between different units of barometric pressure. / GPL-3	noarch
<code>r-rmr2</code>	3.3.1	Supports the map reduce programming model on top of hadoop streaming / Apache 2.0	linux-32, linux-64, osx-64, win-32, win-64
<code>r-rms</code>	5.1_3	Regression modeling, testing, estimation, validation, graphics, prediction, and typesetting by storing enhanced model design attributes in the fit. 'rms' is a collection of functions that assist with and streamline modeling. It also contains functions for binary and ordinal logistic regression models, ordinal models for continuous Y with a variety of distribution families, and the Buckley-James multiple regression model for right-censored responses, and implements penalized maximum likelihood estimation for logistic and ordinary linear models. 'rms' works with almost any regression model, but it was especially written to work with binary or ordinal regression models, Cox regression, accelerated failure time models, ordinary linear models, the Buckley-James model, generalized least squares for serially or spatially correlated observations, generalized linear models, and quantile regression. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
<code>r-rms.gof</code>	1.0	This package can be used to test any simple null hypothesis using the root-mean-square goodness of fit test. Monte Carlo estimation is used to calculate the associated P-value. / GPL-3	noarch
<code>r-rmsfact</code>	0.0.3	Display a randomly selected quote about Richard M. Stallman based on the collection in the 'GNU Octave' function 'fact()' which was aggregated by Jordi Guti��rrez Hermoso based on the (now defunct) site stallmanfacts.com (which is accessible only via < http://archive.org >). / GPL-3	noarch
<code>r-rmthreshold</code>	1.1	An algorithm which can be used to determine an objective threshold for signal-noise separation in large random matrices (correlation matrices, mutual information matrices, network adjacency matrices) is provided. The package makes use of the results of Random Matrix Theory (RMT). The algorithm increments a suppositional threshold monotonically, thereby recording the eigenvalue spacing distribution of the matrix. According to RMT, that distribution undergoes a characteristic change when the threshold properly separates signal from noise. By using the algorithm, the modular structure of a matrix - or of the corresponding network - can be unraveled. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rmtl	0.9	Efficient solvers for 10 regularized multi-task learning algorithms applicable for regression, classification, joint feature selection, task clustering, low-rank learning, sparse learning and network incorporation. Based on the accelerated gradient descent method, the algorithms feature a state-of-art computational complexity $O(1/k^2)$. Sparse model structure is induced by the solving the proximal operator. The detail of the package is described in the paper of Han Cao and Emanuel Schwarz (2018) <doi:10.1093/bioinformatics/bty831>. / GPL-3	noarch
r-rmtstat	0.3	Functions for working with the Tracy-Widom laws and other distributions related to the eigenvalues of large Wishart matrices. The tables for computing the Tracy-Widom densities and distribution functions were computed by Momar Dieng's MATLAB package RMLab (formerly available on his homepage at http://math.arizona.edu/~momar/research.htm). This package is part of a collaboration between Iain Johnstone, Zongming Ma, Patrick Perry, and Morteza Shahram. It will soon be replaced by a package with more accuracy and built-in support for relevant statistical tests. / BSD_3_clause	noarch
r-rmumps	5.2.1	Some basic features of MUMPS (Multifrontal Massively Parallel sparse direct Solver) are wrapped in a class whose methods can be used for sequentially solving a sparse linear system (symmetric or not) with one or many right hand sides (dense or sparse). There is a possibility to do separately symbolic analysis, LU (or LDL^t) factorization and system solving. Third part ordering libraries are included and can be used: PORD, METIS, SCOTCH. MUMPS method was first described in Amestoy et al. (2001) <doi:10.1137/S0895479899358194> and Amestoy et al. (2006) <doi:10.1016/j.parco.2005.07.004>. / GPL-2	linux-64, osx-64, win-64
r-rmutil	1.1.3	A toolkit of functions for nonlinear regression and repeated measurements not to be used by itself but called by other Lindsey packages such as 'gnlm', 'stable', 'growth', 'repeated', and 'event' (available at < http://www.commanster.eu/rcode.html >). / GPL-2	linux-64, osx-64, win-64
r-rmvp	0.99.1	A memory-efficient, visualize-enhanced, parallel-accelerated Genome-Wide Association Study (GWAS) tool. It can (1) effectively process large data, (2) rapidly evaluate population structure, (3) efficiently estimate variance components several algorithms, (4) implement parallel-accelerated association tests of markers three methods, (5) globally efficient design on GWAS process computing, (6) enhance visualization of related information. 'rMVP' contains three models GLM (Alkes Price (2006) <DOI:10.1038/ng1847>), MLM (Jianming Yu (2006) <DOI:10.1038/ng1702>) and FarmCPU (Xiaolei Liu (2016) <doi:10.1371/journal.pgen.1005767>); variance components estimation methods EMMAX (Hyunmin Kang (2008) <DOI:10.1534/genetics.107.080101>), FaSTLMM (method: Christoph Lippert (2011) <DOI:10.1038/nmeth.1681>, R implementation from 'GAPIT2': You Tang and Xiaolei Liu (2016) <DOI:10.1371/journal.pone.0107684> and 'SUPER': Qishan Wang and Feng Tian (2014) <DOI:10.1371/journal.pone.0107684>), and HE regression (Xiang Zhou (2017) <DOI:10.1214/17-AOAS1052>). / Apache License 2.0	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rmysql	0.10.1	A ‘DBI’ interface to ‘MySQL’ / ‘MariaDB’. The ‘RMySQL’ package contains an old implementation based on legacy code from S-PLUS which being phased out. A modern ‘MySQL’ client based on ‘Rcpp’ is available from the ‘RMariaDB’ package. / GPL-2	linux-32, linux-64, osx-64, win-64
r-rnaseqwrapper	1.0.1	This package is designed to streamline several of the common steps for RNA-seq analysis, including differential expression and variant discovery. For the development build, or to contribute changes to this package, please see our repository at https://bitbucket.org/petersmp/rnaseqwrapper/ / GPL-3	noarch
r-rnassqs	0.5.0	Interface to access data via the United States Department of Agriculture’s National Agricultural Statistical Service (NASS) ‘Quick Stats’ web API < https://quickstats.nass.usda.gov/api >. Convenience functions facilitate building queries based on available parameters and valid parameter values. / MIT	noarch
r-rnaturalearthdata	0.1.0	Vector map data from < http://www.naturalearthdata.com/ >. Access functions are provided in the accompanying package ‘rnaturalearth’. / CC0	noarch
r-rnavgraphimagedata	0.0.4	Image data used as examples in the loon R package. / GPL-2	noarch
r-rnavicell	0.2	Provides a set of functions to access a data visualization web service. For more information and a tutorial on how to use it, see https://navicell.curie.fr/pages/nav_web_service.html and https://github.com/sysbio-curie/RNaviCell . / LGPL-2.1	noarch
r-rnbp	0.1.0	Use the < http://api.nbp.pl/ > API through R. Retrieve currency exchange rates and gold prices data published by the National Bank of Poland in form of convenient R objects. / GPL-3	noarch
r-rncbieutlslibs	0.9	Provides the libraries of the EUtills operations for the RNCBI package. / GPL-3	noarch
r-rnd	1.2	Extract the implied risk neutral density from options using various methods. / GPL-2	noarch
r-rndtexexams	1.5	Using as input a ‘LaTeX’ file with a multiple choice exam, this package will produce several versions with randomized contents of the same exam. Functions for grading are also available. / GPL-2	noarch
r-rnentropy	1.2.2	An implementation of a method based on information theory devised for the identification of genes showing a significant variation of expression across multiple conditions. Given expression estimates from any number of RNA-Seq samples and conditions it identifies genes or transcripts with a significant variation of expression across all the conditions studied, together with the samples in which they are over- or under-expressed. Zambelli et al. (2018) <doi:10.1093/nar/gky055>. / GPL-3	noarch
r-rneos	0.3.2	Within this package the XML-RPC API to NEOS < https://neos-server.org/neos/ > is implemented. This enables the user to pass optimization problems to NEOS and retrieve results within R. / GPL-2	noarch
r-rnetcarto	0.2.4	It provides functions to compute the modularity and modularity-related roles in networks. It is a wrapper around the rgraph library (Guimera & Amaral, 2005, doi:10.1038/nature03288). / GPL-2	linux-64, osx-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rnetcdf	1.9_1	An interface to the NetCDF file format designed by Unidata for efficient storage of array-oriented scientific data and descriptions. The R interface is closely based on the C API of the NetCDF library, and it includes calendar conversions from the Unidata UDUNITS library. The current implementation supports all operations on NetCDF datasets in classic and 64-bit offset file formats, and NetCDF4-classic format is supported for reading and modification of existing files. / GPL-2	linux-64, osx-64, win-64
r-rnetlogo	1.0_4	Interface to use and access Wilensky's 'NetLogo' (Wilensky 1999) from R using either headless (no GUI) or interactive GUI mode. Provides functions to load models, execute commands, and get values from reporters. Mostly analogous to the 'NetLogo' 'Mathematica' Link < https://github.com/NetLogo/Mathematica-Link >. / GPL-2	noarch
r-rngforgpd	1.0_2	Generation of univariate and multivariate data that follow the generalized Poisson distribution. The details of the univariate part are explained in Demirtas (2017), and the multivariate part is an extension of the correlated Poisson data generation routine that was introduced in Yahav and Shmueli (2012). / GPL-2 GPL-3	noarch
r-rngsetseed	0.3_2	A function <code>setVectorSeed()</code> is provided. Its argument is a numeric vector of an arbitrary nonzero length, whose components have integer values from $[0, 2^{32}-1]$. The input vector is transformed using AES (Advanced Encryption Standard) algorithm into an initial state of Mersenne-Twister random number generator. The function provides a better alternative to the R base function <code>set.seed()</code> , if the input vector is a single integer. Initializing a stream of random numbers with a vector is a convenient way to obtain several streams, each of which is identified by several integer indices. / GPL-3	linux-64, osx-64, win-64
r-rngtools	1.3.1	Provides a set of functions for working with Random Number Generators (RNGs). In particular, a generic S4 framework is defined for getting/setting the current RNG, or RNG data that are embedded into objects for reproducibility. Notably, convenient default methods greatly facilitate the way current RNG settings can be changed. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rngwell	0.10_5	It is a dedicated package to WELL pseudo random generators, which were introduced in Panneton et al. (2006), "Improved Long-Period Generators Based on Linear Recurrences Modulo 2", ACM Transactions on Mathematical Software. But this package is not intended to be used directly, you are strongly __encouraged__ to use the 'randtoolbox' package, which depends on this package. / BSD_3_clause	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rngwell19937	0.6_0	Long period linear random number generator WELL19937a by F. Panneton, P. L'Ecuyer and M. Matsumoto. The initialization algorithm allows to seed the generator with a numeric vector of an arbitrary length and uses MRG32k5a by P. L'Ecuyer to achieve good quality of the initialization. The output function may be set to provide numbers from the interval (0,1) with 53 (the default) or 32 random bits. WELL19937a is of similar type as Mersenne Twister and has the same period. WELL19937a is slightly slower than Mersenne Twister, but has better equidistribution and bit-mixing properties and faster recovery from states with prevailing zeros than Mersenne Twister. All WELL generators with orders 512, 1024, 19937 and 44497 can be found in randtoolbox package. / file LICENSE (Restricts use)	linux-64, osx-64, win-64
r-rnifti	0.11.1	Provides very fast read and write access to images stored in the NIFTI-1 and ANALYZE-7.5 formats, with seamless synchronisation between compiled C and interpreted R code. Also provides a C/C API that can be used by other packages. Not to be confused with 'RNiftyReg', which performs image registration. / GPL-2	linux-64, osx-64, win-64
r-rnomni	0.7.1	Genetic association tests that use the rank-based inverse normal transformation (INT). These tests are recommend for continuous traits with non-normally distributed residuals. INT-based tests robustly control the type I error in settings where standard linear regression does not. Moreover, INT-based tests dominate standard linear regression in terms of power. INT-based tests may be classified into two types: tests that directly transform the phenotype (D-INT) and tests that transform phenotypic residuals (I-INT). Our omnibus test (O-INT) adaptively combines D-INT and I-INT into a single robust and statistically powerful approach. / GPL-3	linux-64, osx-64, win-64
r-rnpn	0.1.0	Programmatic interface to the Web Service methods provided by the National 'Phenology' Network (< https://usanpn.org/ >), which includes data on various life history events that occur at specific times. / MIT	noarch
r-rnr	0.2.1	Apply sensitivity analysis for offline policy evaluation, as implemented in Jung et al. (2017) <arXiv:1702.04690> based on Rosenbaum and Rubin (1983) < http://www.jstor.org/stable/2345524 >. / GPL-3	noarch
r-rnumera1	0.3	Routines to interact with the Numerai Machine Learning Tournament API < https://numer.ai >. The functionality includes the ability to automatically download the current tournament data, submit predictions, and to get information for your user. General 'GraphQL' queries can also be executed. / GPL-3	noarch
r-roauth	0.9.6	Provides an interface to the OAuth 1.0 specification allowing users to authenticate via OAuth to the server of their choice. / Artistic-2.0	noarch
r-robastda	1.2.0	Includes 'sysdata.rda' file for packages of the 'RobAST' - family of packages; is currently used by package 'RobExtremes' only. / LGPL-3	noarch
r-robcor	0.1_6	Robust pairwise correlations based on estimates of scale, particularly on FastQn one-step M-estimate. / GPL-2	noarch
r-robcp	0.2.4	Provides robust methods to detect change-points in uni- or multivariate time series. They can cope with corrupted data and heavy tails. One can detect changes in location, scale and dependence structure of a possibly multivariate time series. Procedures are based on Huberized versions of CUSUM tests proposed in Duerre and Fried (2019) <arXiv:1905.06201>. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-robeth	2.7.5	Locations problems, M-estimates of coefficients and scale in linear regression, Weights for bounded influence regression, Covariance matrix of the coefficient estimates, Asymptotic relative efficiency of regression M-estimates, Robust testing in linear models, High breakdown point regression, M-estimates of covariance matrices, M-estimates for discrete generalized linear models. / GPL-2	linux-64, osx-64, win-64
r-robfilter	4.1.1	A set of functions to filter time series based on concepts from robust statistics. / GPL-2	linux-64, osx-64, win-64
r-robfitcongraph	0.1.0	Contains a single function named robFitConGraph() which includes two algorithms for robust estimation of scatter matrices subject to zero-constraints in its inverse. The methodology is described in Vogel & Tyler (2014) <doi:10.1093/biomet/asu041>. See robFitConGraph() function documentation for further details. / GPL-3	linux-64, osx-64, win-64
r-robtsvd	1.0	This package provides the function to calculate SVD, regularized SVD, robust SVD and robust regularized SVD method. The robust SVD methods use alternating iteratively reweighted least squares methods. The regularized SVD uses generalized cross validation to choose the optimal smoothing parameters. / GPL-3	noarch
r-robmeta	2.0	Functions for conducting robust variance estimation (RVE) meta-regression using both large and small sample RVE estimators under various weighting schemes. These methods are distribution free and provide valid point estimates, standard errors and hypothesis tests even when the degree and structure of dependence between effect sizes is unknown. Also included are functions for conducting sensitivity analyses under correlated effects weighting and producing RVE-based forest plots. / GPL-2	noarch
r-robustaft	1.4.4	R functions for the computation of the truncated maximum likelihood and the robust accelerated failure time regression for gaussian and log-Weibull case. / GPL-2	linux-64, osx-64, win-64
r-robustbase	0.93.4	Essential Robust Statistics. Tools allowing to analyze data with robust methods. This includes regression methodology including model selections and multivariate statistics where we strive to cover the book Robust Statistics, Theory and Methods by 'Maronna, Martin and Yohai'; Wiley 2006. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-robustblme	0.1.3	Bayesian robust fitting of linear mixed effects models through weighted likelihood equations and approximate Bayesian computation as proposed by Ruli et al. (2017) <arXiv:1706.01752>. / GPL-2	linux-64, osx-64, win-64
r-robustetm	1.0	Testing homogeneity for generalized exponential tilt model. This package includes a collection of functions for (1) implementing methods for testing homogeneity for generalized exponential tilt model; and (2) implementing existing methods under comparison. / GPL-2	linux-64, osx-64, win-64
r-robustgam	0.1.7	This package provides robust estimation for generalized additive models. It implements a fast and stable algorithm in Wong, Yao and Lee (2013). The implementation also contains three automatic selection methods for smoothing parameter. They are designed to be robust to outliers. For more details, see Wong, Yao and Lee (2013). / GPL-2	linux-64, osx-64, win-64
r-robustgasp	0.5.7	Robust parameter estimation and prediction of Gaussian stochastic process emulators. It allows for robust parameter estimation and prediction using Gaussian stochastic process emulator. It also implements the parallel partial Gaussian stochastic process emulator for computer model with massive outputs See the reference: Mengyang Gu and Jim Berger, 2016, Annals of Applied Statistics; Mengyang Gu, Xiaojing Wang and Jim Berger, 2018, Annals of Statistics. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-robustrankaggreg	1.1	Methods for aggregating ranked lists, especially lists of genes. It implements the Robust Rank Aggregation (Kolde et. al in preparation) and some other simple algorithms for the task. RRA method uses a probabilistic model for aggregation that is robust to noise and also facilitates the calculation of significance probabilities for all the elements in the final ranking. / GPL-2	noarch
r-robustreg	0.1.1	Linear regression functions using Huber and bisquare psi functions. Optimal weights are calculated using IRLS algorithm. / GPL-2	linux-64, osx-64, win-64
r-robustx	1.2.4	Robustness – ‘eXperimental’, ‘eXtraneous’, or ‘eXtraordinary’ Functionality for Robust Statistics. In other words, methods which are not yet well established, often related to methods in package ‘robustbase’. / GPL-2	noarch
r-rocc	1.2	Functions for a classification method based on receiver operating characteristics (ROC). Briefly, features are selected according to their ranked AUC value in the training set. The selected features are merged by the mean value to form a metagene. The samples are ranked by their metagene value and the metagene threshold that has the highest accuracy in splitting the training samples is determined. A new sample is classified by its metagene value relative to the threshold. In the first place, the package is aimed at two class problems in gene expression data, but might also apply to other problems. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-roccv</code>	1.2	Cross validate large genetic data while specifying clinical variables that should always be in the model using the function <code>cv()</code> . An ROC plot from the cross validation data with AUC can be obtained using <code>rocplot()</code> , which also can be used to compare different models. Framework was built to handle genetic data, but works for any data. / MIT	noarch
<code>r-rocit</code>	1.1.1	Sensitivity (or recall or true positive rate), false positive rate, specificity, precision (or positive predictive value), negative predictive value, misclassification rate, accuracy, F-score- these are popular metrics for assessing performance of binary classifier for certain threshold. These metrics are calculated at certain threshold values. Receiver operating characteristic (ROC) curve is a common tool for assessing overall diagnostic ability of the binary classifier. Unlike depending on a certain threshold, area under ROC curve (also known as AUC), is a summary statistic about how well a binary classifier performs overall for the classification task. ROCit package provides flexibility to easily evaluate threshold-bound metrics. Also, ROC curve, along with AUC, can be obtained using different methods, such as empirical, binormal and non-parametric. ROCit encompasses a wide variety of methods for constructing confidence interval of ROC curve and AUC. ROCit also features the option of constructing empirical gains table, which is a handy tool for direct marketing. The package offers options for commonly used visualization, such as, ROC curve, KS plot, lift plot. Along with in-built default graphics setting, there are rooms for manual tweak by providing the necessary values as function arguments. ROCit is a powerful tool offering a range of things, yet it is very easy to use. / GPL-3	noarch
<code>r-rocnit</code>	1.0	Non-inferiority test and diagnostic test are very important in clinical trials. This package is to get a p value from the non-inferiority test for ROC curves from diagnostic test. / GPL-3	noarch
<code>r-rococo</code>	1.1.7	Provides the robust gamma rank correlation coefficient as introduced by Bodenhofer, Krone, and Klawonn (2013) <DOI:10.1016/j.ins.2012.11.026> along with a permutation-based rank correlation test. The rank correlation coefficient and the test are explicitly designed for dealing with noisy numerical data. / GPL-2	linux-64, osx-64, win-64
<code>r-rocr</code>	1.0.7	ROC graphs, sensitivity/specificity curves, lift charts, and precision/recall plots are popular examples of trade-off visualizations for specific pairs of performance measures. ROCR is a flexible tool for creating cutoff-parameterized 2D performance curves by freely combining two from over 25 performance measures (new performance measures can be added using a standard interface). Curves from different cross-validation or bootstrapping runs can be averaged by different methods, and standard deviations, standard errors or box plots can be used to visualize the variability across the runs. The parameterization can be visualized by printing cutoff values at the corresponding curve positions, or by coloring the curve according to cutoff. All components of a performance plot can be quickly adjusted using a flexible parameter dispatching mechanism. Despite its flexibility, ROCR is easy to use, with only three commands and reasonable default values for all optional parameters. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-rocwogs</code>	1.0	Function to estimate the ROC Curve of a continuous-scaled diagnostic test with the help of a second imperfect diagnostic test with binary responses. / GPL-2	noarch

Name	Version	Summary/License	Platforms
r-rodam	0.1.6	‘ODAM’ (Open Data for Access and Mining) is a framework that implements a simple way to make research data broadly accessible and fully available for reuse, including by a script language such as R. The main purpose is to make a data set accessible online with a minimal effort from the data provider, and to allow any scientists or bioinformaticians to be able to explore the data set and then extract a subpart or the totality of the data according to their needs. The Rodam package has only one class, ‘odamws’, that provides methods to allow you to retrieve online data using ‘ODAM’ Web Services. This obviously requires that data are implemented according the ‘ODAM’ approach, namely that the data subsets were deposited in the suitable data repository in the form of TSV files associated with their metadata also described in TSV files. See < http://www.slideshare.net/danieljacob771282/odam-open-data-access-and-mining >. / LGPL-3	noarch
r-rodbc	1.3.1	An ODBC database interface. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-rodcbdbi	0.1.1	An implementation of R’s DBI interface using ODBC package as a back-end. This allows R to connect to any DBMS that has a ODBC driver. / MIT	noarch
r-rodcbext	0.3.1	An extension for RODBC package adding support for parameterized queries. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-rode	0.99.6	Show physics, math and engineering students how an ODE solver is made and how effective R classes can be for the construction of the equations that describe natural phenomena. Inspiration for this work comes from the book on Computer Simulations in Physics by Harvey Gould, Jan Tobochnik, and Wolfgang Christian. Book link: < http://www.compadre.org/osp/items/detail.cfm?ID=7375 >. / GPL-2	noarch
r-rodeo	0.7.4	Provides an R6 class and several utility methods to facilitate the implementation of models based on ordinary differential equations. The heart of the package is a code generator that creates compiled ‘Fortran’ (or ‘R’) code which can be passed to a numerical solver. There is direct support for solvers contained in packages ‘deSolve’ and ‘rootSolve’. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rodmm	1.1	This package implements an interface to Oracle Data Mining (ODM). It provides an ideal environment for rapid development of demos and proof of concept data mining studies. It facilitates the prototyping of vertical applications and makes ODM and the RDBMS environment easily accessible to statisticians and data analysts familiar with R but not fluent in SQL or familiar with the database environment. It also facilitates the benchmarking and testing of ODM functionality including the production of summary statistics, performance metrics and graphics. It enables the scripting and control of production data mining methodologies from a high-level environment. Oracle Data Mining (ODM) is an option of Oracle Relational Database Management System (RDBMS) Enterprise Edition (EE). It contains several data mining and data analysis algorithms for classification, prediction, regression, clustering, associations, feature selection, anomaly detection, feature extraction, and specialized analytics. It provides means for the creation, management and operational deployment of data mining models inside the database environment. For more information consult the entry for Oracle Data Mining in Wikipedia (en.wikipedia.org). / LGPL-2	noarch
r-roi	0.3_2	The R Optimization Infrastructure ('ROI') is a sophisticated framework for handling optimization problems in R. More information can be found on the 'ROI' homepage < http://roi.r-forge.r-project.org/ >. / GPL-3	noarch
r-rollbar	0.1.0	Reports errors and messages to Rollbar, the error tracking platform < https://rollbar.com >. / MIT	noarch
r-rolldown	0.1	R Markdown output formats based on JavaScript libraries such as 'Scrollama' (< https://github.com/russellgoldenberg/scrollama >) for storytelling. / MIT	noarch
r-rollregres	0.1.2	Methods for fast rolling and expanding linear regression models. That is, series of linear regression models estimated on either an expanding window of data or a moving window of data. The methods use rank-one updates and downdates of the upper triangular matrix from a QR decomposition (see Dongarra, Moler, Bunch, and Stewart (1979) <doi:10.1137/1.9781611971811>). / GPL-2	linux-64, osx-64, win-64
r-roloc	0.1_1	Functions to convert an R colour specification to a colour name. The user can select and create different lists of colour names and different colour metrics for the conversion. / GPL-2 GPL-3	noarch
r-rolr	1.0.0	Provides fast procedures for exploring all pairs of cutpoints of a single covariate with respect to survival and determining optimal cutpoints using a hierarchical method and various ordered logrank tests. / GPL-3	noarch
r-ronfhir	0.3.1	R on FHIR is an easy to use wrapper around the 'HL7 FHIR' REST API (STU 3). It provides tools to easily read and search resources on a FHIR server and brings the results into the R environment. R on FHIR is based on the FhirClient of the official 'HL7 FHIR .NET API', also made by Firely. / BSD_3_clause	noarch
r-rook	1.1_1	This package contains the Rook specification and convenience software for building and running Rook applications. To get started, be sure and read the 'Rook' help file first. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rootsolve	1.7	Routines to find the root of nonlinear functions, and to perform steady-state and equilibrium analysis of ordinary differential equations (ODE). Includes routines that: (1) generate gradient and jacobian matrices (full and banded), (2) find roots of non-linear equations by the ‘Newton-Raphson’ method, (3) estimate steady-state conditions of a system of (differential) equations in full, banded or sparse form, using the ‘Newton-Raphson’ method, or by dynamically running, (4) solve the steady-state conditions for uni-and multicomponent 1-D, 2-D, and 3-D partial differential equations, that have been converted to ordinary differential equations by numerical differencing (using the method-of-lines approach). Includes fortran code. / GPL-2	linux-64, osx-64, win-64
r-rootwishart	0.4.1	Functions for hypothesis testing in single and double Wishart settings, based on Roy’s largest root. This test statistic is especially useful in multivariate analysis. The computations are based on results by Chiani (2014) <DOI:10.1016/j.jmva.2014.04.002> and Chiani (2016) <DOI:10.1016/j.jmva.2015.10.007>. They use the fact that the CDF is related to the Pfaffian of a matrix that can be computed in a finite number of iterations. This package takes advantage of the Boost and Eigen C libraries to perform multi-precision linear algebra. / GPL-2	linux-64, osx-64, win-64
r-rop	1.0	Trees Classification and Regression using multivariate nodes calculated by an exhaustive numerical approach. We propose a new concept of decision tree, including multivariate knots and non hierarchical pathway. This package’s model uses a multivariate nodes tree that calculates directly a risk score for each observation for the state Y observed. Nguyen JM, Gaultier A, Antonioli D (2015) <doi:10.1016/j.respe.2018.03.088> Castillo JM, Knol AC, Nguyen JM, Khammari A, Saint Jean M, Dreno B (2016) <doi:10.1684/ejd.2016.2826> Vildy S, Nguyen JM, Gaultier A, Khammari A, Dreno B (2017) <doi:10.1684/ejd.2016.2955> Nguyen JM, Gaultier A, Antonioli D (2018) <doi:10.1016/j.respe.2018.03.088>. / GPL (>= 2.0)	noarch
r-rope	1.0	Selects one model with variable selection FDR controlled at a specified level. A q-value for each potential variable is also returned. The input, variable selection counts over many bootstraps for several levels of penalization, is modeled as coming from a beta-binomial mixture distribution. / GPL-3	noarch
r-ropendata	0.1.0	‘Rapid7’ collects ‘cybersecurity’ data and makes it available via their ‘Open Data’ < http://opendata.rapid7.com > portal which has an API. Tools are provided to assist in querying for available data sets and downloading any data set authorized to a free, registered account. / MIT	noarch
r-ropendota	0.1.2	Provides a client for the API of OpenDota. OpenDota is a web service which is provide DOTA2 real time data. Data is collected through the Steam WebAPI. With ROpenDota you can easily grab the latest DOTA2 statistics in R programming such as latest match on official international competition, analyzing your or enemy performance to learn their strategies,etc. Please see < https://github.com/rosdyana/ROpenDota > for more information. / MIT	noarch
r-ropenfigi	0.2.8	Provide a simple interface to Bloomberg’s OpenFIGI API. Please see < https://openfigi.com > for API details and registration. You may be eligible to have an API key to accelerate your loading process. / GPL-3	noarch
r-ropensecretsapi	1.0.1	An R package for the OpenSecrets.org web services API. / LGPL-3	noarch
r-ropenweathermap	1.1	OpenWeatherMap (OWM) < http://openweathermap.org/api > is a service providing weather related data. This package can be used to access current weather data for one location or several locations. It can also be used to forecast weather for 5 days with data for every 3 hours. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-roperators	1.1.0	Provides string arithmetic, reassignment operators, logical operators that handle missing values, and extra logical operators such as floating point equality and all or nothing. The intent is to allow R users to write code that is easier to read, write, and maintain while providing a friendlier experience to new R users from other language backgrounds (such as ‘Python’) who are used to concepts such as <code>x = 1</code> and <code>‘foo’ ‘bar’</code> . / MIT	noarch
r-roptimizely	0.2.0	R package extracts optimizely test results and test information using Optimizely REST API. Only read functionality is supported for analysis and reporting. / GPL-2	noarch
r-rose	0.0.3	The package provides functions to deal with binary classification problems in the presence of imbalanced classes. Synthetic balanced samples are generated according to ROSE (Menardi and Torelli, 2013). Functions that implement more traditional remedies to the class imbalance are also provided, as well as different metrics to evaluate a learner accuracy. These are estimated by holdout, bootstrap or cross-validation methods. / GPL-2	noarch
r-rosetteapi	1.12.1	‘Rosette’ is an API for multilingual text analysis and information extraction. More information can be found at < https://developer.rosette.com >. / Apache License 2.0 file LICENSE	noarch
r-rotationforest	0.1.3	Fit and deploy rotation forest models (Rodriguez, J.J., Kuncheva, L.I., 2006. Rotation forest: A new classifier ensemble method. IEEE Trans. Pattern Anal. Mach. Intell. 28, 1619-1630 <doi:10.1109/TPAMI.2006.211>) for binary classification. Rotation forest is an ensemble method where each base classifier (tree) is fit on the principal components of the variables of random partitions of the feature set. / GPL-2	noarch
r-rotor	0.2.3	Conditionally rotate or back-up files based on their size or the date of the last backup; inspired by the ‘Linux’ utility ‘logrotate’. / MIT	noarch
r-roughsetknowledge-reduction	0.1	Rough Sets were introduced by Zdzislaw Pawlak on his book Rough Sets: Theoretical Aspects of Reasoning About Data. Rough Sets provide a formal method to approximate crisp sets when the set-element belonging relationship is either known or undetermined. This enables the use of Rough Sets for reasoning about incomplete or contradictory knowledge. A decision table is a prescription of the decisions to make given some conditions. Such decision tables can be reduced without losing prescription ability. This package provides the classes and methods for knowledge reduction from decision tables as presented in the chapter 7 of the aforementioned book. This package provides functions for calculating the both the discernibility matrix and the essential parts of decision tables. / MIT	noarch
r-roundhouse	0.0.1	An R wrapper to the ‘Internet Chuck Norris database’ (‘ICNDb’) API for generating random Chuck Norris facts. / GPL-2	noarch
r-rowt	1.1.3	Provides utilities which interact with all R objects as if they were arranged in rows. It allows more consistent and predictable output to common functions, and generalizes a number of utility functions to to be failsafe with any number and type of input objects. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-roxygen2	6.1.1	Generate your Rd documentation, 'NAMESPACE' file, and collation field using specially formatted comments. Writing documentation in-line with code makes it easier to keep your documentation up-to-date as your requirements change. 'Roxygen2' is inspired by the 'Doxygen' system for C. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-rpaci	0.1.1	Analysis of corneal data obtained from a Placido disk corneal topographer with calculation of irregularity indices. A corneal topographer is an ophthalmic clinical device that obtains measurements in the cornea (the anterior part of the eye). A Placido disk corneal topographer makes use of the Placido disk (Rowsey et al. (1981), <doi:10.1001/archophth.1981.03930011093022>, Rand et al. (1997), <doi:10.1016/S0886-3350(99)00355-7>), which produce a circular pattern of measurement nodes. The raw information measured by such a topographer is used by practitioners to analyze curvatures, to study optical aberrations, or to diagnose specific conditions of the eye. The rPACI package allows the calculation of the corneal irregularity indices described in Ramos-Lopez et al. (2013), <doi:10.1097/OPX.0b013e3182843f2a>, and that were firstly introduced in Ramos-Lopez et al. (2011), <doi:10.1097/OPX.0b013e3182843f2a>. It provides a simple interface to read corneal topography data files as exported by a typical Placido disk topographer, to compute the irregularity indices mentioned before, and to display summary plots that are easy to interpret for a clinician. / GPL-3	noarch
r-rpanel	1.1_4	A set of functions to build simple GUI controls for R functions. These are built on the 'tcltk' package. Uses could include changing a parameter on a graph by animating it with a slider or a doublebutton, up to more sophisticated control panels. Some functions for specific graphical tasks, referred to as 'cartoons', are provided. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rpart	4.1_1	Recursive partitioning for classification, regression and survival trees. An implementation of most of the functionality of the 1984 book by Breiman, Friedman, Olshen and Stone. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-rpart.plot	3.0.8	Plot 'rpart' models. Extends plot.rpart() and text.rpart() in the 'rpart' package. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rpart.utils	0.5	This package contains additional tools for working with <code>rpart</code> objects. Most importantly, it includes methods for converting <code>rpart</code> rules into a series of structured tables sufficient for executing the decision tree completely in SQL. / GPL-3	noarch
r-rpartscore	1.0.1	This package contains functions that allow to build classification trees for ordinal responses within the CART framework. The trees are grown using the Generalized Gini impurity function, where the misclassification costs are given by the absolute or squared differences in scores assigned to the categories of the response. Pruning is based on the total misclassification rate or on the total misclassification cost. / GPL-2	noarch
r-rpca	0.2.3	Suppose we have a data matrix, which is the superposition of a low-rank component and a sparse component. Candes, E. J., Li, X., Ma, Y., & Wright, J. (2011). Robust principal component analysis?. Journal of the ACM (JACM), 58(3), 11. prove that we can recover each component individually under some suitable assumptions. It is possible to recover both the low-rank and the sparse components exactly by solving a very convenient convex program called Principal Component Pursuit; among all feasible decompositions, simply minimize a weighted combination of the nuclear norm and of the L1 norm. This package implements this decomposition algorithm resulting with Robust PCA approach. / GPL-2 GPL-3	noarch
r-rpclr	1.0	This package implements the R-PCLR (Random-Penalized Conditional Logistic Regression) algorithm for obtaining variable importance. The algorithm is applicable for the analysis of high dimensional data from matched case-control studies. / GPL-2	noarch
r-rpensemble	0.4	Implements the methodology of Cannings, T. I. and Samworth, R. J. (2017) Random-projection ensemble classification, J. Roy. Stat. Soc., Ser. B. (with discussion), 79, 959–1035. The random projection ensemble classifier is a general method for classification of high-dimensional data, based on careful combination of the results of applying an arbitrary base classifier to random projections of the feature vectors into a lower-dimensional space. The random projections are divided into non-overlapping blocks, and within each block the projection yielding the smallest estimate of the test error is selected. The random projection ensemble classifier then aggregates the results of applying the base classifier on the selected projections, with a data-driven voting threshold to determine the final assignment. / GPL-3	noarch
r-rpexe.rpext	0.0.1	This reduced piecewise exponential survival software implements the likelihood ratio test and backward elimination procedure in Han, Schell, and Kim (2012 <doi:10.1080/19466315.2012.698945>, 2014 <doi:10.1002/sim.5915>), and Han et al. (2016 <doi:10.1111/biom.12590>). Inputs to the program can be either times when events/censoring occur or the vectors of total time on test and the number of events. Outputs of the programs are times and the corresponding p-values in the backward elimination. Details about the model and implementation are given in Han et al. 2014. This program can run in R version 3.2.2 and above. / GPL-3	noarch
r-rphylic	0.1.2	Rphylic provides an R interface for the PHYLIP package. All users of Rphylic will thus first have to install the PHYLIP phylogeny methods program package (Felsenstein 2013). See http://www.phylip.com for more information about installing PHYLIP. / GPL-2	noarch
r-rpinterest	0.3.1	Get information (boards, pins and users) from the Pinterest < http://www.pinterest.com > API. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rpipedrive	0.1.1	R interaction with ‘pipedrive.com API’. All functions were created and documented according to < https://developers.pipedrive.com/docs/api/v1/ >. Created with the objective of offering integration and even the development of ‘APIs’. Making possible to create workflows and easily downloading databases for analysis. / GPL-2	noarch
r-rpivottable	0.3.0	Build powerful pivot tables (aka Pivot Grid, Pivot Chart, Cross-Tab) and dynamically slice & dice / drag ‘n’ drop your data. ‘rpivotTable’ is a wrapper of ‘pivottable’, a powerful open-source Pivot Table library implemented in ‘JavaScript’ by Nicolas Kruchten. Aligned to ‘pivottable’ v2.19.0. / MIT	noarch
r-rplotengine	1.0.7	Generate basic charts either by custom applications, or from a small script launched from the system console, or within the R console. Two ASCII text files are necessary: (1) The graph parameters file, which name is passed to the function ‘rplotengine()’. The user can specify the titles, choose the type of the graph, graph output formats (e.g. png, eps), proportion of the X-axis and Y-axis, position of the legend, whether to show or not a grid at the background, etc. (2) The data to be plotted, which name is specified as a parameter (‘data_filename’) in the previous file. This data file has a tabulated format, with a single character (e.g. tab) between each column, and a headers line located in the first row. Optionally, the file could include data columns for showing confidence intervals. / GPL-2	noarch
r-rpmg	2.2.2	Really Poor Man’s Graphical User Interface, used to create interactive R analysis sessions with simple R commands. / GPL-2	noarch
r-rpmm	1.25	Recursively Partitioned Mixture Model for Beta and Gaussian Mixtures. This is a model-based clustering algorithm that returns a hierarchy of classes, similar to hierarchical clustering, but also similar to finite mixture models. / GPL-2	noarch
r-rpnf	1.0.5	A set of functions to analyze and print the development of a commodity using the Point and Figure (P&F) approach. A P&F processor can be used to calculate daily statistics for the time series. These statistics can be used for deeper investigations as well as to create plots. Plots can be generated as well known X/O Plots in plain text format, and additionally in a more graphical format. / GPL-3	noarch
r-rpoet	1.1.0	Wrapper for the ‘PoetryDB’ API < http://poetrydb.org > that allows for interaction and data extraction from the database in an R interface. The ‘PoetryDB’ API is a database of poetry and poets implemented with ‘MongoDB’ to enable developers and poets to easily access one of the most comprehensive poetry databases currently available. / GPL-2	noarch
r-rppairwisdesign	1.0	Using some association schemes to obtain a new series of resolvable partially pairwise balanced designs (RPPBD) and space-filling designs. / GPL-3	noarch
r-rprime	0.1.0	‘Eprime’ is a set of programs for administering psychological experiments by computer. This package provides functions for loading, parsing, filtering and exporting data in the text files produced by ‘Eprime’ experiments. / GPL-2	noarch
r-rprintf	0.2.1	Provides a set of functions to facilitate building formatted strings under various replacement rules: C-style formatting, variable-based formatting, and number-based formatting. C-style formatting is basically identical to built-in function ‘sprintf’. Variable-based formatting allows users to put variable names in a formatted string which will be replaced by variable values. Number-based formatting allows users to use index numbers to represent the corresponding argument value to appear in the string. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rprobsup	2.1	The A() function calculates the A statistic, a nonparametric measure of effect size for two independent groups thatâ€™s also known as the probability of superiority (Ruscio, 2008), along with its standard error and a confidence interval constructed using bootstrap methods (Ruscio & Mullen, 2012). Optional arguments can be specified to calculate variants of the A statistic developed for other research designs (e.g., related samples, more than two independent groups or related samples; Ruscio & Gera, 2013). <DOI: 10.1037/1082-989X.13.1.19>. <DOI: 10.1080/00273171.2012.658329>. <DOI: 10.1080/00273171.2012.738184>. / MIT	noarch
r-rprojroot	1.3.2	Robust, reliable and flexible paths to files below a project root. The ‘root’ of a project is defined as a directory that matches a certain criterion, e.g., it contains a certain regular file. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rpsychi	0.8	The rpsychi offers a number of functions for psychiatry, psychiatric nursing, clinical psychology. Functions are primarily for statistical significance testing using published work. For example, you can conduct a factorial analysis of variance (ANOVA), which requires only the mean, standard deviation, and sample size for each cell, rather than the individual data. This package covers fundamental statistical tests such as t-test, chi-square test, analysis of variance, and multiple regression analysis. With some exceptions, you can obtain effect size and its confidence interval. These functions help you to obtain effect size from published work, and then to conduct a priori power analysis or meta-analysis, even if a researcher do not report effect size in a published work. / GPL-2	noarch
r-rpublica	0.1.3	Client for accessing data journalism APIs from ProPublica < http://www.propublica.org/ >. / GPL-2	noarch
r-rpushbullet	0.3.2	An R interface to the Pushbullet messaging service which provides fast and efficient notifications (and file transfer) between computers, phones and tablets. An account has to be registered at the site < http://www.pushbullet.com > site to obtain a (free) API key. / GPL-2	noarch
r-rqcc	0.19.8	Constructs robust quality control chart based on the median and Hodges-Lehmann estimators (location) and the median absolute deviation (MAD) and Shamos estimators (scale) which are unbiased with a sample of finite size. For more details, see Park, Kim and Wang (2019)<arXiv:1908.00462>. This work was partially supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (No. NRF-2017R1A2B4004169). / GPL-2 GPL-3	noarch
r-rrate	1.0	Replication Rate (RR) is the probability of replicating a statistically significant association in genome-wide association studies. This R-package provide the estimation method for replication rate which makes use of the summary statistics from the primary study. We can use the estimated RR to determine the sample size of the replication study, and to check the consistency between the results of the primary study and those of the replication study. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rrblup	4.6	Software for genomic prediction with the RR-BLUP mixed model (Endelman 2011, <doi:10.3835/plantgenome2011.08.0024>). One application is to estimate marker effects by ridge regression; alternatively, BLUPs can be calculated based on an additive relationship matrix or a Gaussian kernel. / GPL-3	noarch
r-rtna	1.0	Functions for creating and manipulating RNA secondary structure plots. / GPL-3	noarch
r-rrroad	0.0.5	Computation of the International Roughness Index (IRI) given a longitudinal road profile. The IRI can be calculated for a single road segment or for a sequence of segments with a fixed length (e. g. 100m). For the latter, an overlap of the segments can be selected. The IRI and likewise the algorithms for its determination are defined in Sayers, Michael W; Gillespie, Thomas D; Queiroz, Cesar A.V. 1986. The International Road Roughness Experiment (IRRE) : establishing correlation and a calibration standard for measurements. World Bank technical paper; no. WTP 45. Washington, DC : The World Bank. (ISBN 0-8213-0589-1) available from < http://documents.worldbank.org/curated/en/326081468740204115 >. / MIT	noarch
r-rromeo	0.1.0	Fetches information from the ‘SHERPA/RoMEO’ API < http://www.sherpa.ac.uk/romeo/apimanual.php > which indexes policies of journal regarding the archival of scientific manuscripts before and/or after peer-review as well as formatted manuscripts. / GPL-3	noarch
r-rrpp	0.4.2	Linear model calculations are made for many random versions of data. Using residual randomization in a permutation procedure, sums of squares are calculated over many permutations to generate empirical probability distributions for evaluating model effects. This packaged is described by Collyer & Adams (2018) <doi:10.1111/2041-210X.13029>. Additionally, coefficients, statistics, fitted values, and residuals generated over many permutations can be used for various procedures including pairwise tests, prediction, classification, and model comparison. This package should provide most tools one could need for the analysis of high-dimensional data, especially in ecology and evolutionary biology, but certainly other fields, as well. / GPL-2	noarch
r-rrreg	0.7.0	Univariate and multivariate methods to analyze randomized response (RR) survey designs (e.g., Warner, S. L. (1965). Randomized response: A survey technique for eliminating evasive answer bias. Journal of the American Statistical Association, 60, 63–69, <doi:10.2307/2283137>). Besides univariate estimates of true proportions, RR variables can be used for correlations, as dependent variable in a logistic regression (with or without random effects), or as predictors in a linear regression (Heck, D. W., & Moshagen, M. (2018). RRreg: An R package for correlation and regression analyses of randomized response data. Journal of Statistical Software, 85(2), 1–29, <doi:10.18637/jss.v085.i02>). For simulations and the estimation of statistical power, RR data can be generated according to several models. The implemented methods also allow to test the link between continuous covariates and dishonesty in cheating paradigms such as the coin-toss or dice-roll task (Moshagen, M., & Hilbig, B. E. (2017). The statistical analysis of cheating paradigms. Behavior Research Methods, 49, 724–732, <doi:10.3758/s13428-016-0729-x>). / GPL-3	noarch
r-rrscale	0.1.3	Non-linear transformations of data to better discover latent effects. Applies a sequence of three transformations (1) a Gaussianizing transformation, (2) a Z-score transformation, and (3) an outlier removal transformation. / GPL-3	noarch
r-rsadb	1.0	The package contains all the data sets related to the book written by the maintainer of the package. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rsampling	0.1.1	Resampling Stats (http://www.resample.com) is an add-in for running randomization tests in Excel worksheets. The workflow is (1) to define a statistic of interest that can be calculated from a data table, (2) to randomize rows and/or columns of a data table to simulate a null hypothesis and (3) to score the value of the statistic from many randomizations. The relative frequency distribution of the statistic in the simulations is then used to infer the probability of the observed value being generated by the null process (probability of Type I error). This package intends to translate this logic for R for teaching purposes. Keeping the original workflow is favored over performance. / GPL-2	noarch
r-rsrules	1.0	Implements the Gibbs sampling algorithm to randomly sample association rules with one pre-chosen item as the consequent from a transaction dataset. The Gibbs sampling algorithm was proposed in G. Qian, C.R. Rao, X. Sun and Y. Wu (2016) <DOI:10.1073/pnas.1604553113>. / GPL-3	noarch
r-rsatscan	0.3.92	SaTScan(TM) (http://www.satscan.org) is software for finding regions in Time, Space, or Time-Space that have excess risk, based on scan statistics, and uses Monte Carlo hypothesis testing to generate P-values for these regions. The rsatscan package provides functions for writing R data frames in SaTScan-readable formats, for setting SaTScan parameters, for running SaTScan in the OS, and for reading the files that SaTScan creates. / GPL-3	noarch
r-saucelabs	0.1.6	Retrieve, update, delete job information from < https://saucelabs.com/ >. Poll the 'SauceLabs' services current status and access supported platforms. Send and retrieve files from 'SauceLabs' and manage tunnels associated with 'SauceConnect'. / GPL-3	noarch
r-rsca	3.0	A statistical tool for multivariate modeling and clustering using stepwise cluster analysis. The modeling output of rSCA is constructed as a cluster tree to represent the complicated relationships between multiple dependent and independent variables. A free tool (named rSCA Tree Generator) for visualizing the cluster tree from rSCA is also released and it can be downloaded at < https://rscatree.weebly.com/ >. / GPL-2	noarch
r-rscala	3.2.15	'Scala' < http://www.scala-lang.org/ > is embedded in 'R' and callbacks from 'Scala' to 'R' are available. Support is provided to write 'R' packages that access 'Scala'. After installation, please run 'rscala::scalaConfig()'. / Apache License 2.0 file LICENSE	noarch
r-rsconnect	0.8.13	Programmatic deployment interface for 'RPods', 'shinyapps.io', and 'RStudio Connect'. Supported content types include R Markdown documents, Shiny applications, Plumber APIs, plots, and static web content. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rsdmx	0.5.1	Set of classes and methods to read data and metadata documents exchanged through the Statistical Data and Metadata Exchange (SDMX) framework, currently focusing on the SDMX XML standard format (SDMX-ML). / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rse	1.3	A Bayesian-weighted estimator and two unweighted estimators are developed to estimate the number of newly found rare species in additional ecological samples. Among these methods, the Bayesian-weighted estimator and an unweighted (Chao-derived) estimator are of high accuracy and recommended for practical applications. Technical details of the proposed estimators have been well described in the following paper: Shen TJ, Chen YH (2018) A Bayesian weighted approach to predicting the number of newly discovered rare species. Conservation Biology, In press. / GPL-3	noarch
r-rseedcalc	1.3	Estimate the percentage of seeds in a seedlot that contain stacks of genetically modified traits. Estimates are calculated using a multinomial group testing model with maximum likelihood estimation of the parameters. / GPL-2	noarch
r-rsem	0.4.6	A robust procedure is implemented to estimate means and covariance matrix of multiple variables with missing data using Huber weight and then to estimate a structural equation model. / GPL-2	noarch
r-rserve	1.7.3	Rserve acts as a socket server (TCP/IP or local sockets) which allows binary requests to be sent to R. Every connection has a separate workspace and working directory. Client-side implementations are available for popular languages such as C/C and Java, allowing any application to use facilities of R without the need of linking to R code. Rserve supports remote connection, user authentication and file transfer. A simple R client is included in this package as well. / GPL-2 file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-rsfa	1.04	Slow Feature Analysis in R, ported to R based on the matlab versions SFA toolkit 1.0 by Pietro Berkes and SFA toolkit 2.8 by Wolfgang Konen for matlab. / GPL-2	noarch
r-rsitecatalyst	1.4.15	Functions for interacting with the Adobe Analytics API V1.4 (< https://api.omniture.com/admin/1.4/rest/ >). / MIT	noarch
r-rskey	0.4.1	Create custom keyboard shortcuts to examine code selected in the 'Rstudio' editor. F3 can for example yield 'str(selection)' and F7 open the source code of CRAN and base package functions on 'github'. / GPL-2	noarch
r-rslp	0.1.0	Implements the Stemming Algorithm for the Portuguese Language <DOI:10.1109/SPIRE.2001.10024>. / MIT	noarch
r-rslurm	0.4.0	Functions that simplify submitting R scripts to a Slurm workload manager, in part by automating the division of embarrassingly parallel calculations across cluster nodes. / GPL-3	noarch
r-rsm	2.10	Provides functions to generate response-surface designs, fit first- and second-order response-surface models, make surface plots, obtain the path of steepest ascent, and do canonical analysis. A good reference on these methods is Chapter 10 of Wu, C-F J and Hamada, M (2009) Experiments: Planning, Analysis, and Parameter Design Optimization ISBN 978-0-471-69946-0. / GPL-2	noarch
r-rsmartlyio	0.1.3	Aims at loading Facebook and Instagram advertising data from 'Smartly.io' into R. 'Smartly.io' is an online advertising service that enables advertisers to display commercial ads on social media networks (see < http://www.smartly.io/ > for more information). The package offers an interface to query the 'Smartly.io' API and loads data directly into R for further data processing and data analysis. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rsocrata	1.7.9	Provides easier interaction with ‘Socrata’ open data portals < http://dev.socrata.com >. Users can provide a ‘Socrata’ data set resource URL, or a ‘Socrata’ Open Data API (SoDA) web query, or a ‘Socrata’ human-friendly URL, returns an R data frame. Converts dates to ‘POSIX’ format and manages throttling by ‘Socrata’. Users can upload data to ‘Socrata’ portals directly from R. / MIT	noarch
r-rsoi	0.5.0	Downloads Southern Oscillation Index, Oceanic Nino Index, North Pacific Gyre Oscillation data, North Atlantic Oscillation and Arctic Oscillation. Data sources are described in the README file. / GPL-3	noarch
r-rspc	1.2.2	Implementation of Nelson rules for control charts in ‘R’. The ‘Rspc’ implements some Statistical Process Control methods, namely Levey-Jennings type of I (individuals) chart, Shewhart C (count) chart and Nelson rules (as described in Montgomery, D. C. (2013) Introduction to statistical quality control. Hoboken, NJ: Wiley.). Typical workflow is taking the time series, specify the control limits, and list of Nelson rules you want to evaluate. There are several options how to modify the rules (one sided limits, numerical parameters of rules, etc.). Package is also capable of calculating the control limits from the data (so far only for i-chart and c-chart are implemented). / GPL-3	noarch
r-rspde	0.4.6	Functions that compute rational approximations of fractional elliptic stochastic partial differential equations. The package also contains functions for common statistical usage of these approximations. The main reference for the methods is Bolin and Kirchner (2019) <arXiv:1711.04333>, which can be generated by the citation function in R. / GPL-3	noarch
r-rspincalc	1.0.2	Conversion between attitude representations: DCM, Euler angles, Quaternions, and Euler vectors. Plus conversion between 2 Euler angle set types (xyx, yzy, xzx, xzy, yxz, yzx, xzy, yxz, zyx). Fully vectorized code, with warnings/errors for Euler angles (singularity, out of range, invalid angle order), DCM (orthogonality, not proper, exceeded tolerance to unity determinant) and Euler vectors(not unity). Also quaternion and other useful functions. Based on SpinCalc by John Fuller and SpinConv by Paolo de Leva. / GPL-3	noarch
r-rsps	1.0	Provides functions for estimating power or sample size for RNA-Seq studies. Empirical approach is used and the data is assumed to be count in nature. The underlying distribution of data is assumed to be Poisson or negative binomial. The package contains 6 function; 4 functions provide estimates of sample size or power for Poisson and Negative Binomial distribution; 2 functions provide plots of power for given sample size or sample size for given power. / GPL-2	noarch
r-rsq	1.1	Calculate generalized R-squared, partial R-squared, and partial correlation coefficients for generalized linear models (including quasi models with well defined variance functions). / GPL-2	noarch
r-rsqlite	2.1.1	Embeds the ‘SQLite’ database engine in R and provides an interface compliant with the ‘DBI’ package. The source for the ‘SQLite’ engine is included. / LGPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rssop	1.1	Reservoir Systems Standard Operation Policy. A system for simulation of supply reservoirs. It proposes functionalities for plotting and evaluation of supply reservoirs systems. / GPL-2	noarch
r-rstack	1.0.0	An extremely simple stack data type, implemented with ‘R6’ classes. The size of the stack increases as needed, and the amortized time complexity is O(1). The stack may contain arbitrary objects. / MIT	noarch
r-rstackdeque	1.1.1	Provides fast, persistent (side-effect-free) stack, queue and deque (double-ended-queue) data structures. While deques include a superset of functionality provided by queues, in these implementations queues are more efficient in some specialized situations. See the documentation for rstack, rdeque, and rpqueue for details. / MIT	noarch
r-rstan	2.18.2	User-facing R functions are provided to parse, compile, test, estimate, and analyze Stan models by accessing the header-only Stan library provided by the ‘StanHeaders’ package. The Stan project develops a probabilistic programming language that implements full Bayesian statistical inference via Markov Chain Monte Carlo, rough Bayesian inference via ‘variational’ approximation, and (optionally penalized) maximum likelihood estimation via optimization. In all three cases, automatic differentiation is used to quickly and accurately evaluate gradients without burdening the user with the need to derive the partial derivatives. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
r-rstantools	1.5.1	Provides various tools for developers of R packages interfacing with ‘Stan’ < http://mc-stan.org >, including functions to set up the required package structure, S3 generics and default methods to unify function naming across ‘Stan’-based R packages, and vignettes with recommendations for developers. / GPL-3	noarch
r-rstata	1.1.1	A simple R -> Stata interface allowing the user to execute Stata commands (both inline and from a .do file) from R. / GPL-3	noarch
r-rstatscn	1.1.3	R interface for china national data < http://data.stats.gov.cn/ >, some convenient functions for accessing the national data are provided. / Apache License 2.0	noarch
r-rstorm	1.0	While streaming processing provides opportunities to deal with extremely large and ever growing data sets in (near) real time, the development of streaming algorithms for complex models is often cumbersome: the software packages that facilitate streaming processing in production environments do not provide statisticians with the simulation, estimation, and plotting tools they are used to. Developers of streaming algorithms would thus benefit from the flexibility of [R] to create, plot and compute data while developing streaming algorithms. Package RStorm implements a streaming architecture modeled on Storm for easy development and testing of streaming algorithms in [R]. RStorm is not intended as a production package, but rather a development tool for streaming algorithms. / GPL-2	noarch
r-rstripe	0.1	A convenience interface for communicating with the Stripe payment processor to accept payments online. See < https://stripe.com > for more information. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rstudioapi	0.10	Access the RStudio API (if available) and provide informative error messages when it's not. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rsubgroup	0.6	A collection of efficient and effective tools and algorithms for subgroup discovery and analytics. The package integrates an R interface to the org.vikamine.kernel library of the VIKAMINE system (http://www.vikamine.org) implementing subgroup discovery, pattern mining and analytics in Java. / GPL-3	noarch
r-rsurfer	0.2	The software suite, 'Freesurfer', is a open-source software suite involving the segmentation of brain MRIs (see < http://freesurfer.net/ > for more information). This package provides functionality to import the data generated by 'Freesurfer'; functions to easily manipulate the data; and provides brain specific normalisation commonly used when studying structural brain MRIs. This package has been designed using an installation of and data generated from 'Freesurfer' version 5.3. / MIT	noarch
r-rsurrogate	2.0	Provides functions to estimate the proportion of treatment effect on the primary outcome that is explained by the treatment effect on the surrogate marker. / GPL-3	noarch
r-rsvd	1.0.2	Low-rank matrix decompositions are fundamental tools and widely used for data analysis, dimension reduction, and data compression. Classically, highly accurate deterministic matrix algorithms are used for this task. However, the emergence of large-scale data has severely challenged our computational ability to analyze big data. The concept of randomness has been demonstrated as an effective strategy to quickly produce approximate answers to familiar problems such as the singular value decomposition (SVD). The rsvd package provides several randomized matrix algorithms such as the randomized singular value decomposition (rsvd), randomized principal component analysis (rpca), randomized robust principal component analysis (rrpca), randomized interpolative decomposition (rid), and the randomized CUR decomposition (rcur). In addition several plot functions are provided. The methods are discussed in detail by Erichson et al. (2016) <arXiv:1608.02148>. / GPL-3	noarch
r-rt.test	1.18.7	Performs one-sample t-test based on robustified statistics using median/MAD (TA) and Hodges-Lehmann/Shamos (TB). For more details, see Park and Wang (2018)<arXiv:1807.02215>. This work was partially supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (No. NRF-2017R1A2B4004169). / GPL-2 GPL-3	noarch
r-rt3	0.1.2	Play the classic game of tic-tac-toe (naughts and crosses). / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rtape	2.2	Storing huge data in RData format causes problems because of the necessity to load the whole file to the memory in order to access and manipulate objects inside such file; rtape is a simple solution to this problem. The package contains several wrappers of R built-in serialize/unserialize mechanism allowing user to quickly append objects to a tape-like file and later iterate over them requiring only one copy of each stored object to reside in memory a time. / GPL-2	noarch
r-rtauchen	1.0	Discretize AR(1) process following Tauchen (1986) < http://www.sciencedirect.com/science/article/pii/0165176586901680 >. A discrete Markov chain that approximates in the sense of weak convergence a continuous-valued univariate Autoregressive process of first order is generated. It is a popular method used in economics and in finance. / GPL-2	noarch
r-rtaxometrics	2.3	We provide functions to perform taxometric analyses. This package contains 44 functions, but only 5 should be called directly by users. CheckData() should be run prior to any taxometric analysis to ensure that the data are appropriate for taxometric analysis. RunTaxometrics() performs taxometric analyses for a sample of data. RunCCFIPProfile() performs a series of taxometric analyses to generate a CCFI profile. CreateData() generates a sample of categorical or dimensional data. ClassifyCases() assigns cases to groups using the base-rate classification method. / MIT	noarch
r-rtconnect	0.1.4	Tools for analyzing sales report files of iTunes Connect. / GPL-3	noarch
r-rtde	0.2_0	Robust tail dependence estimation for bivariate models. This package is based on two papers by the authors: 'Robust and bias-corrected estimation of the coefficient of tail dependence' and 'Robust and bias-corrected estimation of probabilities of extreme failure sets'. This work was supported by a research grant (VKR023480) from VILLUM FONDEN and an international project for scientific cooperation (PICS-6416). / GPL-2	noarch
r-rtematres	0.2	Exploit controlled vocabularies organized on tematres servers. / GPL-3	noarch
r-rtensor	1.4	A set of tools for creation, manipulation, and modeling of tensors with arbitrary number of modes. A tensor in the context of data analysis is a multidimensional array. rTensor does this by providing a S4 class 'Tensor' that wraps around the base 'array' class. rTensor provides common tensor operations as methods, including matrix unfolding, summing/averaging across modes, calculating the Frobenius norm, and taking the inner product between two tensors. Familiar array operations are overloaded, such as index subsetting via '[' and element-wise operations. rTensor also implements various tensor decomposition, including CP, GLRAM, MPCA, PVD, and Tucker. For tensors with 3 modes, rTensor also implements transpose, t-product, and t-SVD, as defined in Kilmer et al. (2013). Some auxiliary functions include the Khatri-Rao product, Kronecker product, and the Hamadard product for a list of matrices. / GPL-2	noarch
r-rtephra	0.1	Models and displays tephra transport through custom (windy, turbulent, heterogeneous) atmosphere over custom topography. Includes a Lagrangian (particle-tracking) tephra transport model and a function to save snapshots of model as png files. / GPL-3	noarch
r-rttexturemetrics	1.1	This package contains several functions for calculation of texture metrics for Grey Level Co-occurrence matrices / GPL-2	noarch
r-rtf	0.4_14	A set of R functions to output Rich Text Format (RTF) files with high resolution tables and graphics that may be edited with a standard word processor such as Microsoft Word. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rticles	0.10	A suite of custom R Markdown formats and templates for authoring journal articles and conference submissions. / GPL-3	noarch
r-rtika	1.22	Extract text or metadata from over a thousand file types, using Apache Tika < https://tika.apache.org/ >. Get either plain text or structured XHTML content. / Apache License 2.0 file LICENSE	noarch
r-rtnmin	2016_7	Truncated Newton function minimization with bounds constraints based on the ‘Matlab’/‘Octave’ codes of Stephen Nash. / GPL-2	noarch
r-rtorch	0.0.3	‘R’ implementation and interface of the Machine Learning platform ‘PyTorch’ < https://pytorch.org/ > developed in ‘Python’. It requires a ‘conda’ environment with ‘torch’ and ‘torchvision’ to provide ‘PyTorch’ functions, methods and classes. The key object in ‘PyTorch’ is the tensor which is in essence a multidimensional array. These tensors are fairly flexible to perform calculations in CPUs as well as ‘GPUs’ to accelerate the process. / MIT	noarch
r-trim	2.0.6	The TRIM model is widely used for estimating growth and decline of animal populations based on (possibly sparsely available) count data. The current package is a reimplement of the original TRIM software developed at Statistics Netherlands by Jeroen Pannekoek. See < https://www.cbs.nl/en-gb/society/nature-and-environment/indices-and-trends%2d%2dtrim%2d%2d > for more information about TRIM. / EUPL	noarch
r-rts	1.0_49	This framework aims to provide classes and methods for manipulating and processing of raster time series data (e.g. a time series of satellite images). / GPL-3	noarch
r-rtson	1.3	TSON, short for Typed JSON, is a binary-encoded serialization of JSON like document that support JavaScript typed data (https://github.com/tercen/TSON). / Apache License Version 2.0	noarch
r-rtplot	0.1.1	A fast and elegant time series visualization package. In addition to the standard R plot types, this package supports candle sticks, open-high-low-close, and volume plots. Useful for visualizing any time series data, e.g., stock prices and technical indicators. / MIT	noarch
r-rtwalk	1.8.0	The ‘t-walk’ is a general-purpose MCMC sampler for arbitrary continuous distributions that requires no tuning. / GPL-3	noarch
r-rtype	0.1_1	A strong type system for R which supports symbol declaration and assignment with type checking and condition checking. / MIT	noarch
r-runit	0.4.32	R functions implementing a standard Unit Testing framework, with additional code inspection and report generation tools. / GPL-2	linux-64, noarch, osx-64, win-64
r-runiversal	1.0.2	This package contains some functions for converting R objects to Java style variables and XML. Generated Java code is interpretable by dynamic Java libraries such as Beanshell. Calling R externally and handling the Java or XML output is an other way to call R from other languages without native interfaces. For a Java implementation of this approach visit http://www.mhsatman.com/rcaller.php and http://stdioe.blogspot.com/search/label/rcaller / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-runstats	1.0.1	Provides methods for fast computation of running sample statistics for time series. These include: (1) mean, (2) standard deviation, and (3) variance over a fixed-length window of time-series, (4) correlation, (5) covariance, and (6) Euclidean distance (L2 norm) between short-time pattern and time-series. Implemented methods utilize Convolution Theorem to compute convolutions via Fast Fourier Transform (FFT). / GPL-3	noarch
r-ruta	1.1.0	Implementation of several unsupervised neural networks, from building their architecture to their training and evaluation. Available networks are auto-encoders including their main variants: sparse, contractive, denoising, robust and variational, as described in Charte et al. (2018) <doi:10.1016/j.inffus.2017.12.007>. / GPL-3	noarch
r-rv	2.3.3	Implements a simulation-based random variable class and a suite of methods for extracting parts of random vectors, calculating extremes of random vectors, and generating random vectors under a variety of distributions following Kerman and Gelman (2007) <doi:10.1007/s11222-007-9020-4>. / GPL-2	noarch
r-rvcheck	0.1.3	Check latest release version of R and R package (both in ‘CRAN’, ‘Bioconductor’ or ‘Github’). / Artistic-2.0	noarch
r-rversions	1.1.0	Query the main ‘R’ ‘SVN’ repository to find the versions ‘r-release’ and ‘r-oldrel’ refer to, and also all previous ‘R’ versions and their release dates. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rvest	0.3.3	Wrappers around the ‘xml2’ and ‘httr’ packages to make it easy to download, then manipulate, HTML and XML. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-rvhpdt	3.0	To detecting rare variants for binary traits using general pedigrees, the pedigree disequilibrium tests are proposed by collapsing rare haplotypes/variants with/without weights. To run the test, MERLIN is needed in Linux for haplotyping. / GPL-2	noarch
r-rviennacl	1.7.1	‘ViennaCL’ is a free open-source linear algebra library for computations on many-core architectures (GPUs, MIC) and multi-core CPUs. The library is written in C and supports ‘CUDA’, ‘OpenCL’, and ‘OpenMP’ (including switches at runtime). I have placed these libraries in this package as a more efficient distribution system for CRAN. The idea is that you can write a package that depends on the ‘ViennaCL’ library and yet you do not need to distribute a copy of this code with your package. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rviewgraph	1.2	This is an ‘R’ interface to Alun Thomas’s ‘ViewGraph’ ‘Java’ graph viewing program. It takes a graph specified as an incidence matrix, list of edges, or in ‘igraph’ format and runs a graphical user interface that shows an animation of a force directed algorithm positioning the vertices in two dimensions. It works well for graphs of various structure of up to a few thousand vertices. It’s not fazed by graphs that comprise several components. The coordinates can be read as an ‘igraph’ style layout matrix at any time. The user can mess with the layout using a mouse, preferably one with 3 buttons, and some keyed commands. The ‘Java’ program ‘ViewGraph’ is contained in Alun Thomas’s ‘JPS-GCS’ collection of ‘Java’ programs for statistical genetics and computational statistics. The homepage for ‘JPSGCS’ is < http://www-genepi.med.utah.edu/~alun/software/index.html >. The documentation page for ‘ViewGraph’ is at < http://www-genepi.med.utah.edu/~alun/software/docs/ViewGraph.html >. / GPL-2	noarch
r-rvtdt	1.0	Used to compute population controls weighted rare variants transmission distortion test / GPL-3	noarch
r-rwars	1.0.0	Provides functions to retrieve and reformat data from the ‘Star Wars’ API (SWAPI) < https://swapi.co/ >. / MIT	noarch
r-rwc	1.11	Code to facilitate simulation and inference when connectivity is defined by underlying random walks. Methods for spatially-correlated pairwise distance data are especially considered. This provides core code to conduct analyses similar to that in Hanks and Hooten (2013) <doi:10.1080/01621459.2012.724647>. / GPL-2	noarch
r-rweblogo	1.0.3	RWebLogo is a wrapper for the WebLogo python package that allows generating of customised sequence logos. Sequence logos are graphical representations of the sequence conservation of nucleotides (in a strand of DNA/RNA) or amino acids (in protein sequences). Each logo consists of stacks of symbols, one stack for each position in the sequence. The overall height of the stack indicates the sequence conservation at that position, while the height of symbols within the stack indicates the relative frequency of each amino or nucleic acid at that position. In general, a sequence logo provides a richer and more precise description of, for example, a binding site, than would a consensus sequence. / BSD_3_clause	noarch
r-rwekajars	3.9.3	External jars required for package ‘RWeka’. / GPL-2	noarch
r-rwhois	1.0.3	Queries data from WHOIS servers. / MIT	noarch
r-rwinsteps	1.0_1	Facilitates communication between R and the Rasch modeling software Winsteps. Currently includes functions for reading and writing command files, sending them to Winsteps, reading and writing data according to command file specifications, reading output into R, and plotting various results. / GPL-2	noarch
r-rwishart	0.1.1	An expansion of R’s ‘stats’ random wishart matrix generation. This package allows the user to generate singular, Uhlig and Harald (1994) <doi:10.1214/aos/1176325375>, and pseudo wishart, Diaz-Garcia, et al.(1997) <doi:10.1006/jmva.1997.1689>, matrices. In addition the user can generate wishart matrices with fractional degrees of freedom, Adhikari (2008) <doi:10.1061/(ASCE)0733-9399(2008)134:12(1029)>, commonly used in volatility modeling. Users can also use this package to create random covariance matrices. / GPL-2	noarch
r-rworldxtra	1.01	High resolution vector country boundaries derived from Natural Earth data, can be plotted in rworldmap. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-rxkcd	1.8.2	Visualize your favorite XKCD comic strip directly from R. XKCD < https://xkcd.com > web comic content is provided under the Creative Commons Attribution-NonCommercial 2.5 License. / GPL-2	noarch
r-rxnat	1.0.6	Allows communication with Extensible Neuroimaging Archive Toolkit < https://www.xnat.org >. 'Rxnat' is using the 'XNAT' REST API to perform data queries and download images. / GPL-2	noarch
r-rxseq	0.99.3	Analysis of combined total and allele specific reads from the reciprocal cross study with RNA-seq data. / GPL-2	noarch
r-rxshrink	1.1	Identify and display TRACES for a specified shrinkage path and determine the extent of shrinkage most likely, under normal distribution theory, to produce an optimal reduction in MSE Risk in estimates of regression (beta) coefficients. Alternative estimates are also provided when ill-conditioned (nearly multicollinear) models yield OLS estimates with wrong numerical signs. / GPL-3	noarch
r-ryandextranslate	1.0	'Yandex Translate' (https://translate.yandex.com/) is a statistical machine translation system. The system translates separate words, complete texts, and webpages. This package can be used to detect language from text and to translate it to supported target language. For more info: https://tech.yandex.com/translate/doc/dg/concepts/About-docpage/ . / MIT	noarch
r-rym	0.5.2	Allows work with 'Management API' for load counters, segments, filters, user permissions and goals list from Yandex Metrika, 'Reporting API' allows you to get information about the statistics of site visits and other data without using the web interface, 'Logs API' allows to receive non-aggregated data and 'Compatible with Google Analytics Core Reporting API v3' allows receive information about site traffic and other data using field names from Google Analytics Core API. For more information see official documents < https://tech.yandex.ru/metrika/doc/api2/concept/about-docpage/ >. / GPL-2	noarch
r-ryoudaotranslate	1.0	You can use this package to translate thousands of words. The Youdao translation open API is applied in this package. But, it just translates less than 1000 English words into Chinese. / GPL-2	noarch
r-ryotheria	1.0.3	A programmatic interface to web-services of YouTheria. YouTheria is an online database of mammalian trait data < http://www.utheria.org/ >. / MIT	noarch
r-rzabbix	0.1.0	R interface to the 'Zabbix API' data < https://www.zabbix.com/documentation/3.0/manual/api/reference >. Enables easy and direct communication with 'Zabbix API' from 'R'. / GPL-2	noarch
r-rzeit2	0.2.3	Interface to gather newspaper articles from 'DIE ZEIT' and 'ZEIT ONLINE', based on a multilevel query < http://developer.zeit.de/ >. A personal API key is required for usage. / MIT	noarch
r-rzmq	0.9.6	Interface to the 'ZeroMQ' lightweight messaging kernel (see < http://www.zeromq.org/ > for more information). / GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-s20x	3.1.28	A set of functions used in teaching STATS 201/208 Data Analysis at the University of Auckland. The functions are designed to make parts of R more accessible to a large undergraduate population who are mostly not statistics majors. / GPL-2	noarch
r-sabarsi	0.1.0	Implements a new approach ‘SABARSI’ described in Wang et al., A Statistical Approach of Background Removal and Spectrum Identification for SERS Data (Unpublished). Sabarsi forms a pipeline for SERS (surface-enhanced Raman scattering) data analysis including background removal, signal detection, signal integration, and cross-experiment comparison. The background removal algorithm, the very first step of SERS data analysis, takes into account the change of background shape. / GPL-3	noarch
r-sac	1.0.1	Semiparametric empirical likelihood ratio based test of changepoint with one-change or epidemic alternatives with data-based model diagnostic / GPL-2	noarch
r-sacobra	1.1	Performs surrogate-assisted optimization for expensive black-box constrained problems. / GPL-2	noarch
r-sadeg	1.0.0	We analyzed the nucleotide composition of genes with a special emphasis on stability of DNA sequences. Besides, in a variety of different organisms unequal use of synonymous codons, or codon usage bias, occurs which also show variation among genes in the same genome. Seemingly, codon usage bias is affected by both selective constraints and mutation bias which allows and enables us to examine and detect changes in these two evolutionary forces between genomes or along one genome. Therefore, we determined the codon adaptation index (CAI), effective number of codons (ENC) and codon usage analysis with calculation of the relative synonymous codon usage (RSCU), and subsequently predicted the translation efficiency and accuracy through GC-rich codon usages. Furthermore, we estimated the relative stability of the DNA sequence following calculation of the average free energy (Delta G) and Dimer base-stacking energy level. / GPL-3	noarch
r-sae	1.2	Functions for small area estimation. / GPL-2	noarch
r-saemix	2.2	The SAEMIX package implements the Stochastic Approximation EM algorithm for parameter estimation in (non)linear mixed effects models. The SAEM algorithm: - computes the maximum likelihood estimator of the population parameters, without any approximation of the model (linearisation, quadrature approximation,...), using the Stochastic Approximation Expectation Maximization (SAEM) algorithm, - provides standard errors for the maximum likelihood estimator - estimates the conditional modes, the conditional means and the conditional standard deviations of the individual parameters, using the Hastings-Metropolis algorithm. Several applications of SAEM in agronomy, animal breeding and PKPD analysis have been published by members of the Monolix group (< http://group.monolix.org/ >). / GPL-2	noarch
r-saery	1.0	A complete set of functions to calculate several EBLUP (Empirical Best Linear Unbiased Predictor) estimators and their mean squared errors. All estimators are based on an area-level linear mixed model introduced by Rao and Yu in 1994 (see documentation). The REML method is used for fitting this model. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-safd	2.1	The aim of the package is to provide some basic functions for doing statistics with one dimensional Fuzzy Data (in the form of polygonal fuzzy numbers). In particular, the package contains functions for the basic operations on the class of fuzzy numbers (sum, scalar product, mean, median, Hukuhara difference) as well as for calculating (Bertoluzza) distance and sample variance. Moreover a function to simulate fuzzy random variables and bootstrap tests for the equality of means is included. Version 2.1 fixes some bugs of previous versions. / GPL-2	noarch
r-saic	1.0	Computes the Akaike information criterion for the generalized linear models (logistic regression, Poisson regression, and Gaussian graphical models) estimated by the lasso. / GPL-2	noarch
r-saltsampler	1.1.0	The SALTSampler package facilitates Monte Carlo Markov Chain (MCMC) sampling of random variables on a simplex. A Self-Adjusting Logit Transform (SALT) proposal is used so that sampling is still efficient even in difficult cases, such as those in high dimensions or with parameters that differ by orders of magnitude. Special care is also taken to maintain accuracy even when some coordinates approach 0 or 1 numerically. Diagnostic and graphic functions are included in the package, enabling easy assessment of the convergence and mixing of the chain within the constrained space. / BSD_3_clause	noarch
r-salty	0.1.0	Take real or simulated data and salt it with errors commonly found in the wild, such as pseudo-OCR errors, Unicode problems, numeric fields with nonsensical punctuation, bad dates, etc. / MIT	noarch
r-sample.size	1.0	Computes the required sample size using the optimal designs with multiple constraints proposed in Mayo et al.(2010). This optimal method is designed for two-arm, randomized phase II clinical trials, and the required sample size can be optimized either using fixed or flexible randomization allocation ratios. / GPL-2	noarch
r-samplesize	0.2_4	Computes sample size for Student's t-test and for the Wilcoxon-Mann-Whitney test for categorical data. The t-test function allows paired and unpaired (balanced / unbalanced) designs as well as homogeneous and heterogeneous variances. The Wilcoxon function allows for ties. / GPL-2	noarch
r-samplesize4clinicaltrials	0.1.0	The design of phase 3 clinical trials can be classified into 4 types: (1) Testing for equality;(2) Superiority trial;(3) Non-inferiority trial; and (4) Equivalence trial according to the goals. Given that none of the available packages combines these designs in a single package, this package has made it possible for researchers to calculate sample size when comparing means or proportions in phase 3 clinical trials with different designs. The ssc function can calculate the sample size with pre-specified type 1 error rate,statistical power and effect size according to the hypothesis testing framework. Furthermore, effect size is comprised of true treatment difference and non-inferiority or equivalence margins which can be set in ssc function. (Reference: Yin, G. (2012). Clinical Trial Design: Bayesian and Frequentist Adaptive Methods. John Wiley & Sons.) / GPL-2	noarch
r-samplesizecmh	0.0.0	Calculates the power and sample size for Cochran-Mantel-Haenszel tests. There are also several helper functions for working with probability, odds, relative risk, and odds ratio values. / GPL-2 GPL-3	noarch
r-samplesizelogisticcasecontrol	0.0.6	To determine sample size for case-control studies to be analyzed using logistic regression. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-samplesizemeans	1.1	A set of R functions for calculating sample size requirements using three different Bayesian criteria in the context of designing an experiment to estimate a normal mean or the difference between two normal means. Functions for calculation of required sample sizes for the Average Length Criterion, the Average Coverage Criterion and the Worst Outcome Criterion in the context of normal means are provided. Functions for both the fully Bayesian and the mixed Bayesian/likelihood approaches are provided. / GPL-2	noarch
r-samplesizeproportions	1.0	A set of R functions for calculating sample size requirements using three different Bayesian criteria in the context of designing an experiment to estimate the difference between two binomial proportions. Functions for calculation of required sample sizes for the Average Length Criterion, the Average Coverage Criterion and the Worst Outcome Criterion in the context of binomial observations are provided. In all cases, estimation of the difference between two binomial proportions is considered. Functions for both the fully Bayesian and the mixed Bayesian/likelihood approaches are provided. / GPL-2	noarch
r-samplingdatacrt	1.0	Package provides the possibility to sampling complete datasets from a normal distribution to simulate cluster randomized trials for different study designs. / GPL-3	noarch
r-sandwich	2.5.1	Model-robust standard error estimators for cross-sectional, time series, clustered, panel, and longitudinal data. / GPL-2 GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-sanon	1.5	There are several functions to implement the method for analysis in a randomized clinical trial with strata with following key features. A stratified Mann-Whitney estimator addresses the comparison between two randomized groups for a strictly ordinal response variable. The multivariate vector of such stratified Mann-Whitney estimators for multivariate response variables can be considered for one or more response variables such as in repeated measurements and these can have missing completely at random (MCAR) data. Non-parametric covariance adjustment is also considered with the minimal assumption of randomization. The p-value for hypothesis test and confidence interval are provided. / GPL-2	noarch
r-sarp.moodle	0.3.10	Provides a set of basic functions for creating Moodle XML output files suited for importing questions in Moodle (a learning management system, see < https://moodle.org/ > for more information). / Artistic-2.0	noarch
r-sas7bdat	0.5	Read SAS files in the sas7bdat data format. / GPL-2	noarch
r-sascii	1.0	Using any importation code designed for SAS users to read ASCII files into sas7bdat files, the SAScii package parses through the INPUT block of a (.sas) syntax file to design the parameters needed for a read.fwf function call. This allows the user to specify the location of the ASCII (often a .dat) file and the location of the .sas syntax file, and then load the data frame directly into R in just one step. / GPL-2	noarch
r-sasmarkdown	0.4.3	Settings and functions to extend the ‘knitr’ ‘SAS’ engine. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sasmixed	1.0_4	Data sets and sample lmer analyses corresponding to the examples in Littell, Milliken, Stroup and Wolfinger (1996), SAS System for Mixed Models, SAS Institute. / GPL-2	noarch
r-saspect	0.1_1	A statistical method for significant analysis of comparative proteomics based on LC-MS/MS Experiments / GPL-2	noarch
r-sautomata	0.1.0	Machine learning provides algorithms that can learn from data and make inferences or predictions. Stochastic automata is a class of input/output devices which can model components. This work provides implementation an inference algorithm for stochastic automata which is similar to the Viterbi algorithm. Moreover, we specify a learning algorithm using the expectation-maximization technique and provide a more efficient implementation of the Baum-Welch algorithm for stochastic automata. This work is based on Inference and learning in stochastic automata was by Karl-Heinz Zimmermann(2017) <doi:10.12732/ijpam.v11i5i3.15>. / GPL-3	noarch
r-saver	1.1.1	An implementation of a regularized regression prediction and empirical Bayes method to recover the true gene expression profile in noisy and sparse single-cell RNA-seq data. See Huang M, et al (2018) <doi:10.1038/s41592-018-0033-z> for more details. / GPL-2	noarch
r-saves	0.5	The purpose of this package is to be able to save and load only the needed variables/columns of a dataframe in special binary files (tar archives) - which seems to be a lot faster method than loading the whole binary object (RData files) via load() function, or than loading columns from SQLite/MySQL databases via SQL commands (see vignettes). Performance gain on SSD drives is a lot more sensible compared to basic load() function. The performance improvement gained by loading only the chosen variables in binary format can be useful in some special cases (e.g. where merging data tables is not an option and very different datasets are needed for reporting), but be sure if using this package that you really need this, as non-standard file formats are used! / AGPL-3	noarch
r-sbf	1.1.1	Smooth Backfitting for additive models using Nadaraya-Watson estimator / GPL-2	noarch
r-sbgcop	0.980	Estimation and inference for parameters in a Gaussian copula model, treating the univariate marginal distributions as nuisance parameters as described in Hoff (2007) <doi:10.1214/07-AOAS107>. This package also provides a semi-parametric imputation procedure for missing multivariate data. / GPL-2	noarch
r-sbl	0.1.0	Implements sparse Bayesian learning method for QTL mapping and genome-wide association studies. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sbrect	0.26	The package uses fitting axes-aligned rectangles to a time series in order to find structural breaks. The algorithm enclose the time series in a number of axes-aligned rectangles and tries to minimize their area and number. As these are conflicting aims, the user has to specify a parameter alpha in [0.0,1.0]. Values close to 0 result in more breakpoints, values close to 1 in fewer. The left edges of the rectangles are the breakpoints. The package supplies two methods, <code>computeBreakPoints(series,alpha)</code> which returns the indices of the break points and <code>computeRectangles(series,alpha)</code> which returns the rectangles. The algorithm is randomised; it uses a genetic algorithm. Therefore, the break point sequence found can be different in different executions of the method on the same data, especially when used on longer series of some thousand observations. The algorithm uses a range-tree as background data structure which makes it very fast and suited to analyse series with millions of observations. A detailed description can be found in Paul Fischer, Astrid Hilbert, Fast detection of structural breaks, Proceedings of Compstat 2014. / GPL-2	noarch
r-sbsdif	0.1.0	Calculates a Satorra-Bentler scaled chi-squared difference test between nested models that were estimated using maximum likelihood (ML) with robust standard errors, which cannot be calculated the traditional way. For details see Satorra & Bentler (2001) <doi:10.1007/bf02296192> and Satorra & Bentler (2010) <doi:10.1007/s11336-009-9135-y>. This package may be particularly helpful when used in conjunction with ‘Mplus’ software, specifically when implementing the complex survey option. In such cases, the model estimator in ‘Mplus’ defaults to ML with robust standard errors. / MIT	noarch
r-scagnostics	0.2.4	Calculates graph theoretic scagnostics. Scagnostics describe various measures of interest for pairs of variables, based on their appearance on a scatterplot. They are useful tool for discovering interesting or unusual scatterplots from a scatterplot matrix, without having to look at every individual plot. / file LICENSE (FOSS)	noarch
r-scales	1.0.0	Graphical scales map data to aesthetics, and provide methods for automatically determining breaks and labels for axes and legends. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-scalreg	1.0.1	Algorithms for fitting scaled sparse linear regression and estimating precision matrices. / GPL-2	noarch
r-scaml	1.2.5	Routines for generalized additive modelling under shape constraints on the component functions of the linear predictor (Pya and Wood, 2015) <doi:10.1007/s11222-013-9448-7>. Models can contain multiple shape constrained (univariate and/or bivariate) and unconstrained terms. The routines of <code>gam()</code> in package ‘mgcv’ are used for setting up the model matrix, printing and plotting the results. Penalized likelihood maximization based on Newton-Raphson method is used to fit a model with multiple smoothing parameter selection by GCV or UBRE/AIC. / GPL-2	noarch
r-scatterd3	0.9	Creates ‘D3’ ‘JavaScript’ scatterplots from ‘R’ with interactive features : panning, zooming, tooltips, etc. / GPL-3	noarch
r-scatterplot3d	0.3.4	Plots a three dimensional (3D) point cloud. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-scbmeanfd	1.2.2	Statistical methods for estimating and inferring the mean of functional data. The methods include simultaneous confidence bands, local polynomial fitting, bandwidth selection by plug-in and cross-validation, goodness-of-fit tests for parametric models, equality tests for two-sample problems, and plotting functions. / GPL-3	noarch
r-scdensity	1.0.2	Implements methods for obtaining kernel density estimates subject to a variety of shape constraints (unimodality, bimodality, symmetry, tail monotonicity, bounds, and constraints on the number of inflection points). Enforcing constraints can eliminate unwanted waves or kinks in the estimate, which improves its subjective appearance and can also improve statistical performance. The main function <code>scdensity()</code> is very similar to the <code>density()</code> function in ‘stats’, allowing shape-restricted estimates to be obtained with little effort. The methods implemented in this package are described in Wolters and Braun (2017) <doi:10.1080/03610918.2017.1288247>, Wolters (2012) <doi:10.18637/jss.v047.i06>, and Hall and Huang (2002) <http://www3.stat.sinica.edu.tw/statistica/j12n4/j12n41/j12n41.htm>. See the <code>scdensity()</code> help for full citations. / GPL-2	noarch
r-scdhlm	0.3.1	Provides a set of tools for estimating hierarchical linear models and effect sizes based on data from single-case designs. Functions are provided for calculating standardized mean difference effect sizes that are directly comparable to standardized mean differences estimated from between-subjects randomized experiments, as described in Hedges, Pustejovsky, and Shadish (2012) <DOI:10.1002/jrsm.1052>; Hedges, Pustejovsky, and Shadish (2013) <DOI:10.1002/jrsm.1086>; and Pustejovsky, Hedges, and Shadish (2014) <DOI:10.3102/1076998614547577>. Includes an interactive web interface. / GPL-3	noarch
r-scenario	1.0	Uses the neural gas algorithm to construct a scenario tree for use in multi-stage stochastic programming. The primary input is a set of initial scenarios or realizations of a disturbance. The scenario tree nodal structure must be predefined using a scenario tree nodal partition matrix. / GPL-2	noarch
r-schoenberg	2.0.2	Functions for creating and manipulating 12-tone (i.e., dodecaphonic) musical matrices using Arnold Schoenberg’s (1923) serialism technique. This package can generate random 12-tone matrices and can generate matrices using a pre-determined sequence of notes. / GPL-3	noarch
r-schoolmath	0.4	This package contains functions and datasets for math taught in school. A main focus is set to prime-calculation / GPL-2	noarch
r-schorsch	1.6	Offers a helping hand to psychologists and other behavioral scientists who routinely deal with experimental data from factorial experiments. It includes several functions to format output from other R functions according to the style guidelines of the APA (American Psychological Association). This formatted output can be copied directly into manuscripts to facilitate data reporting. These features are backed up by a toolkit of several small helper functions, e.g., offering out-of-the-box outlier removal. The package lends its name to Georg Schorsch Schuessler, ingenious technician at the Department of Psychology III, University of Wuerzburg. For details on the implemented methods, see Roland Pfister and Markus Janczyk (2016) <doi: 10.20982/tqmp.12.2.p147>. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-schumaker	1.1	This is a shape preserving spline <doi:10.1137/0720057> which is guaranteed to be monotonic and concave or convex if the data is monotonic and concave or convex. It does not use any optimisation and is therefore quick and smoothly converges to a fixed point in economic dynamics problems including value function iteration. It also automatically gives the first two derivatives of the spline and options for determining behaviour when evaluated outside the interpolation domain. / MIT	noarch
r-scico	1.1.0	Colour choice in information visualisation is important in order to avoid being misled by inherent bias in the used colour palette. The ‘scico’ package provides access to the perceptually uniform and colour-blindness friendly palettes developed by Fabio Crameri and released under the Scientific Colour-Maps moniker. The package contains 24 different palettes and includes both diverging and sequential types. / MIT	noarch
r-scientotext	0.1	It involves bibliometric indicators calculation from bibliometric data. It also deals pattern analysis using the text part of bibliometric data. The bibliometric data are obtained from mainly Web of Science and Scopus. / GPL-3	noarch
r-scifigure	0.2	Users may specify what fundamental qualities of a new study have or have not changed in an attempt to reproduce or replicate an original study. A comparison of the differences is visualized. Visualization approach follows ‘Patil’, ‘Peng’, and ‘Leek’ (2016) <doi:10.1101/066803>. / MIT	noarch
r-scina	1.2.0	An automatic cell type detection and assignment algorithm for single cell RNA-Seq and Cytof/FACS data. ‘SCINA’ is capable of assigning cell type identities to a pool of cells profiled by scRNA-Seq or Cytof/FACS data with prior knowledge of markers, such as genes and protein symbols that are highly or lowly expressed in each category. See Zhang Z, et al (2019) <doi:10.3390/genes10070531> for more details. / GPL-2	noarch
r-sciplot	1.1_1	A collection of functions that creates graphs with error bars for data collected from one-way or higher factorial designs. / GPL-2	noarch
r-sciviews	0.9_1	Functions to install SciViews additions to R, and more tools. / GPL-2	noarch
r-scma	1.3.0	Perform meta-analysis of single-case experiments, including calculating various effect size measures (SMD, PND, PEM and NAP) and probability combining (additive and multiplicative method), as discussed in Bulte and Onghena (2013) <doi:10.22237/jmasm/1383280020>. / GPL-2	noarch
r-scoreggum	1.0	Estimate GGUM Person Parameters Using Pre-Calibrated Item Parameters and Binary or Graded Disagree-Agree Responses / GPL-2	noarch
r-scorer2	0.99.0	This package contains the functions necessary to run the SCORER 2.0 algorithm. SCORER 2.0 can be used to differentiate between parallel dimeric and trimeric coiled-coil sequence, which are the two most more frequent coiled-coil structures observed naturally. As such, SCORER 2.0 is particularly useful for researchers looking to characterize novel coiled-coil sequences. It may also be used to assist in the structural characterization of synthetic coiled-coil sequences. Also included in this package are functions that allows the user to retrain the SCORER 2.0 algorithm using user-defined training data. / GPL-2	noarch
r-scoring	0.6	Evaluating probabilistic forecasts via proper scoring rules. scoring implements the beta, power, and pseudospherical families of proper scoring rules, along with ordered versions of the latter two families. Included among these families are popular rules like the Brier (quadratic) score, logarithmic score, and spherical score. For two-alternative forecasts, also includes functionality for plotting scores that one would obtain under specific scoring rules. / GPL-2	noarch
r-scottknott	1.2_7	Division of an ANOVA experiment treatment means into homogeneous distinct groups using the clustering method of Scott & Knott. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-scperf	1.1.1	Implements different inventory models, the bullwhip effect and other supply chain performance variables. Marchena Marlene (2010) <arXiv:1009.3977>. / GPL-3	noarch
r-scrabble	1.0	Given a word will produce that word's scrabble score. Unlike many naive implementations this package takes into consideration the distribution of letter in scrabble. So a word like 'zzz' will be scored '10' rather than '30'. / MIT License	noarch
r-scrap	1.1	A utility to webscrape the in-house careers of members of the European parliament, from its website < http://www.europarl.europa.eu >. / GPL-3	noarch
r-scraper	0.1.6	Tools for Scraping Data from Web-Based Documents / GPL-2	noarch
r-screenclean	1.0.1	Routines for a collection of screen-and-clean type variable selection procedures, including UPS and GS. / GPL-2	noarch
r-scrime	1.3.5	Tools for the analysis of high-dimensional data developed/implemented at the group Statistical Complexity Reduction In Molecular Epidemiology (SCRIME). Main focus is on SNP data. But most of the functions can also be applied to other types of categorical data. / GPL-2	noarch
r-scriptests	1.0.1	Support for using .Rt (transcript) tests in the tests directory of a package. Provides more convenience and features than the standard .R/Rout.save tests. Tests can be run under R CMD check and also interactively. Provides source.pkg() for quickly loading code, DLLs, and data from a package for use in an edit/compile/test development cycle. / GPL-3	noarch
r-scriptexec	0.3.1	Run complex native scripts with a single command, similar to system commands. / Apache License 2.0	noarch
r-scriptname	1.0.1	A small set of functions wrapping up the call stack and command line inspection needed to determine a running script's filename from within the script itself. / MIT	noarch
r-scripturs	0.1.0	Full text, in data frames containing one row per verse, of the Standard Works of The Church of Jesus Christ of Latter-day Saints (LDS). These are the Old Testament, (KJV), the New Testament (KJV), the Book of Mormon, the Doctrine and Covenants, and the Pearl of Great Price. / MIT	noarch
r-scrobber	0.1.0	'Last.fm' < https://www.last.fm > is a music platform focussed on building a detailed profile of a users listening habits. It does this by 'scrobbling' (recording) every track you listen to on other platforms ('spotify', 'youtube', 'soundcloud' etc) and transferring them to your 'Last.fm' database. This allows 'Last.fm' to act as a complete record of your entire listening history. 'scrobber' provides helper functions to download and analyse your listening history in R. / GPL-3	noarch
r-scrselect	1.3.3	Contains four functions used in the DIC-tau_g procedure. SCRSELECT() and SCRSELECTRUN() uses Stochastic Search Variable Selection to select important covariates in the three hazard functions of a semi-competing risks model. These functions perform the Gibbs sampler for variable selection and a Metropolis-Hastings-Green sampler for the number of split points and parameters for the three baseline hazard function. The function SCRSELECT() returns the posterior sample of all quantities sampled in the Gibbs sampler after a burn-in period to a desired file location, while the function SCRSELECTRUN() returns posterior values of important quantities to the DIC-Tau_g procedure in a list. The function DICTAUG() returns a list containing the DIC values for the unique models visited by the DIC-Tau_g grid search. The function ReturnModel() uses SCRSELECTRUN() and DICTAUG() to return a summary of the posterior coefficient vectors for the optimal model along with saving this posterior sample to a desired path location. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-scrt	1.3.0	Design single-case phase, alternation and multiple-baseline experiments, and conduct randomization tests on data gathered by means of such designs, as discussed in Bulte and Onghena (2013) <doi:10.22237/jmasm/1383280020>. / GPL-2	noarch
r-sdaa	0.1_3	Functions and Datasets from Lohr, S. (1999), Sampling: Design and Analysis, Duxbury. / GPL-3	noarch
r-sdat	1.1	Test the global null in linear models using marginal approach. / GPL-2	linux-64, osx-64, win-64
r-sdcspatial	0.1.1	Privacy protected raster maps can be created from spatial point data. Protection methods include smoothing of dichotomous variables by de Jonge and de Wolf (2016) <doi:10.1007/978-3-319-45381-1_9>, continuous variables by de Wolf and de Jonge (2018) <doi:10.1007/978-3-319-99771-1_23>, suppressing revealing values and a generalization of the quad tree method by Suñé, Rovira, Ibáñez and Farré (2017) <doi:10.2901/EUROSTAT.C2017.001>. / GPL-2	noarch
r-sdde	1.0.1	Compares the evolution of an original network X to an augmented network Y by counting the number of Shortcuts, Detours, Dead Ends (SDDE), equal paths and disconnected nodes. / GPL-3	linux-64, osx-64, win-64
r-sddpack	0.9	The semidiscrete decomposition (SDD) approximates a matrix as a weighted sum of outer products formed by vectors with entries constrained to be in the set $\{-1, 0, 1\}$. / GPL-2	noarch
r-sdef	1.7	Performs two tests to evaluate if the experiments are associated and returns a list of interesting features common to all the experiments. / GPL-2	noarch
r-sdm	1.0_67	An extensible framework for developing species distribution models using individual and community-based approaches, generate ensembles of models, evaluate the models, and predict species potential distributions in space and time. For more information, please check the following paper: Naimi, B., Araujo, M.B. (2016) <doi:10.1111/ecog.01881>. / GPL-3	noarch
r-sdmtools	1.1_22	This packages provides a set of tools for post processing the outcomes of species distribution modeling exercises. It includes novel methods for comparing models and tracking changes in distributions through time. It further includes methods for visualizing outcomes, selecting thresholds, calculating measures of accuracy and landscape fragmentation statistics, etc.. This package was made possible in part by financial support from the Australian Research Council & ARC Research Network for Earth System Science. / GPL-3	osx-64, win-64
r-sdmvspecies	0.3.2	A software package help user to create virtual species for species distribution modelling. It includes several methods to help user to create virtual species distribution map. Those maps can be used for Species Distribution Modelling (SDM) study. SDM use environmental data for sites of occurrence of a species to predict all the sites where the environmental conditions are suitable for the species to persist, and may be expected to occur. / AGPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sdnet	2.4.1	Fitting discrete Bayesian networks using soft-discretized data. Soft-discretization is based on mixture of normal distributions. Also implemented is a supervised Bayesian network learning employing Kullback-Leibler divergence. For more information see Balov (2013) <DOI:10.1186/1755-8794-6-S3-S1>. / GPL-2	linux-64, osx-64, win-64
r-sdpt3r	0.3	Solves the general Semi-Definite Linear Programming formulation using an R implementation of SDPT3 (K.C. Toh, M.J. Todd, and R.H. Tutuncu (1999) <doi:10.1080/10556789908805762>). This includes problems such as the nearest correlation matrix problem (Higham (2002) <doi:10.1093/imanum/22.3.329>), D-optimal experimental design (Smith (1918) <doi:10.2307/2331929>), Distance Weighted Discrimination (Marron and Todd (2012) <doi:10.1198/016214507000001120>), as well as graph theory problems including the maximum cut problem. Technical details surrounding SDPT3 can be found in R.H Tutuncu, K.C. Toh, and M.J. Todd (2003) <doi:10.1007/s10107-002-0347-5>. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-sdt	1.0.0	Functions for self-determination motivation theory (SDT) to compute measures of motivation internalization, motivation simplex structure, and of the original and adjusted self-determination or relative autonomy index. SDT was introduced by Deci and Ryan (1985) <doi:10.1007/978-1-4899-2271-7>. See package?SDT for an overview. / GPL-2	noarch
r-sdtoolkit	2.33	Implements algorithms to help with scenario discovery - currently only modified version of the the Patient Rule Induction Method. / GPL-3	noarch
r-sdwd	1.0.2	Formulates a sparse distance weighted discrimination (SDWD) for high-dimensional classification and implements a very fast algorithm for computing its solution path with the L1, the elastic-net, and the adaptive elastic-net penalties. / GPL-2	linux-64, osx-64, win-64
r-seacarb	3.2.12	Calculates parameters of the seawater carbonate system and assists the design of ocean acidification perturbation experiments. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-sealasso	0.1_2	Standard error adjusted adaptive lasso (SEA-lasso) is a version of the adaptive lasso, which incorporates OLS standard error to the L1 penalty weight. This method is intended for variable selection under linear regression settings ($n > p$). This new weight assignment strategy is especially useful when the collinearity of the design matrix is a concern. / GPL-2	noarch
r-searchable	0.3.3	Provides functionality for searching / subsetting and slicing named objects using 'stringr/i'-style modifiers by case (in)sensitivity, regular expressions or fixed expressions; searches uses the standard '[' operator and allows specification of default search behavior to either the search target (named object) and/or the search pattern. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-searcher</code>	0.0.4	Provides a search interface to look up terms on ‘Google’, ‘Bing’, ‘DuckDuckGo’, ‘Startpage’, ‘StackOverflow’, ‘RStudio Community’, ‘GitHub’, and ‘BitBucket’. Upon searching, a browser window will open with the aforementioned search results. / GPL-2	noarch
<code>r-searchtrees</code>	0.5.2	This package provides an implementation of the QuadTree data structure. It uses this to implement fast k-Nearest Neighbor and Rectangular range lookups in 2 dimensions. The primary target is high performance interactive graphics. / LGPL-3	linux-64, osx-64, win-64
<code>r-seas</code>	0.5.2	Capable of deriving seasonal statistics, such as normals, and analysis of seasonal data, such as departures. This package also has graphics capabilities for representing seasonal data, including boxplots for seasonal parameters, and bars for summed normals. There are many specific functions related to climatology, including precipitation normals, temperature normals, cumulative precipitation departures and precipitation interarrivals. However, this package is designed to represent any time-varying parameter with a discernible seasonal signal, such as found in hydrology and ecology. / GPL-2	linux-64, osx-64, win-64
<code>r-seasic</code>	0.1	This package conducts Score Equity Assessment (SEA; Dorans, 2004) by calculating and plotting multiple SEA indices as introduced by a variety of authors and summarized by Huggins and Penfield (2012). / GPL-3	noarch
<code>r-seasonal</code>	1.7.0	Easy-to-use interface to X-13-ARIMA-SEATS, the seasonal adjustment software by the US Census Bureau. It offers full access to almost all options and outputs of X-13, including X-11 and SEATS, automatic ARIMA model search, outlier detection and support for user defined holiday variables, such as Chinese New Year or Indian Diwali. A graphical user interface can be used through the ‘seasonalview’ package. Uses the X-13-binaries from the ‘x13binary’ package. / GPL-3	noarch
<code>r-secr</code>	3.2.1	Functions to estimate the density and size of a spatially distributed animal population sampled with an array of passive detectors, such as traps, or by searching polygons or transects. Models incorporating distance-dependent detection are fitted by maximizing the likelihood. Tools are included for data manipulation and model selection. / GPL-2	linux-64, osx-64, win-64
<code>r-secret</code>	1.0.0	Allow sharing sensitive information, for example passwords, ‘API’ keys, etc., in R packages, using public key cryptography. / MIT	noarch
<code>r-secure</code>	0.5	Sequential factor extraction via co-sparse unit-rank estimation (SeCURE). / GPL (>= 3.0)	linux-64, osx-64, win-64
<code>r-securitytxt</code>	0.1.1	When security risks in web services are discovered by independent security researchers who understand the severity of the risk, they often lack the channels to properly disclose them. As a result, security issues may be left unreported. The ‘security.txt’ ‘Web Security Policies’ specification defines an ‘IETF’ draft standard < https://tools.ietf.org/html/draft-foudil-securitytxt-00 > to help organizations define the process for security researchers to securely disclose security vulnerabilities. Tools are provided to help identify and parse ‘security.txt’ files to enable analysis of the usage and adoption of these policies. / MIT	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-seeclickfixr	1.1.0	Provides a wrapper to access data from the SeeClickFix web API for R. SeeClickFix is a central platform employed by many cities that allows citizens to request their city's services. This package creates several functions to work with all the built-in calls to the SeeClickFix API. Allows users to download service request data from numerous locations in easy-to-use dataframe format manipulable in standard R functions. / GPL-3	noarch
r-seedcalc	1.0.0	Functions to calculate seed germination and seedling emergence and growth indexes. The main indexes for germination and seedling emergence, considering the time for seed germinate are: T10, T50 and T90, in Farooq et al. (2005) <10.1111/j.1744-7909.2005.00031.x>; and MGT, in Labouriau (1983). Considering the germination speed are: Germination Speed Index, in Maguire (1962), Mean Germination Rate, in Labouriau (1983); considering the homogeneity of germination are: Coefficient of Variation of the Germination Time, in Carvalho et al. (2005) <10.1590/S0100-84042005000300018>, and Variance of Germination, in Labouriau (1983); Uncertainty, in Labouriau and Valadares (1976) <ISSN:0001-3765>; and Synchrony, in Primack (1980). The main seedling indexes are Growth, in Sako (2001), Uniformity, in Sako (2001) and Castan et al. (2018) <doi:10.1590/1678-992x-2016-0401>; and Vigour, in Medeiros and Pereira (2018) <doi:10.1590/1983-40632018v4852340>. / GPL-2	noarch
r-seedwater	1.0	Bringing together tools for modeling drying and soaking (rehydration) kinetics of seeds. This package contains several widely used predictive models (e.g.: da Silva et al., 2018). As these are nonlinear, the functions are interactive-based and easy-to-use. Least squares estimates are obtained with just a few visual adjustments of the initial parameter values. Reference: da Silva AR et al. (2018) <doi:10.2134/agronj2017.07.0373>. / GPL-2	noarch
r-seer2r	1.0	read and write SEER*STAT data files / GPL-2	noarch
r-seermapper2010east	1.2.0	Provides supplemental 2010 census tract boundary package for 23 states without Seer Registries that are east of the Mississippi river for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. Census data and is in public domain. / GPL-2	noarch
r-seermapper2010regs	1.2.0	Provides supplemental 2010 census tract boundaries of the 15 states containing Seer Registries for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. 2010 Census data and is in public domain. / GPL-2	noarch
r-seermapper2010west	1.2.0	Provides supplemental 2010 census tract boundaries for the 14 states without Seer Registries that are west of the Mississippi river for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. 2010 Census data and is in public domain. / GPL-2	noarch
r-seermappereast	1.2.0	Provides supplemental 2000 census tract boundaries for the 23 states without Seer Registries that are east of the Mississippi river for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. Census data and is in the public domain. / GPL-2	noarch
r-seermapperregs	1.2.0	Provides supplemental 2000 census tract boundaries for the 15 states containing Seer Registries for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. Census data and is in the public domain. / GPL-2	noarch
r-seermapperwest	1.2.0	Provides supplemental 2000 census tract boundaries for the 14 states without Seer Registries that are west of the Mississippi river for use with the 'SeerMapper' package. The data contained in this package is derived from U. S. Census data and is in the public domain. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-segmag	1.2.4	Contains functions that help to determine event boundaries in event segmentation experiments by bootstrapping a critical segmentation magnitude under the null hypothesis that all key presses were randomly distributed across the experiment. Segmentation magnitude is defined as the sum of Gaussians centered at the times of the segmentation key presses performed by the participants. Within a participant, the maximum of the overlaid Gaussians is used to prevent an excessive influence of a single participant on the overall outcome (e.g. if a participant is pressing the key multiple times in succession). Further functions are included, such as plotting the results. / GPL-3	linux-64, osx-64, win-64
r-segmented	1.0_0	Given a regression model, segmented ‘updates’ it by adding one or more segmented (i.e., piece-wise linear) relationships. Several variables with multiple breakpoints are allowed. The estimation method is discussed in Muggeo (2003, <doi:10.1002/sim.1545>) and illustrated in Muggeo (2008, < https://www.r-project.org/doc/Rnews/Rnews_2008-1.pdf >). An approach for hypothesis testing is presented in Muggeo (2016, <doi:10.1080/00949655.2016.1149855>), and interval estimation for the breakpoint is discussed in Muggeo (2017, <doi:10.1111/anzs.12200>). / GPL-3	noarch
r-segmentier	0.1.2	A dynamic programming solution to segmentation based on maximization of arbitrary similarity measures within segments. The general idea, theory and this implementation are described in Machne, Murray & Stadler (2017) <doi:10.1038/s41598-017-12401-8>. In addition to the core algorithm, the package provides time-series processing and clustering functions as described in the publication. These are generally applicable where a <i>k-means</i> clustering yields meaningful results, and have been specifically developed for clustering of the Discrete Fourier Transform of periodic gene expression data (‘circadian’ or ‘yeast metabolic oscillations’). This clustering approach is outlined in the supplemental material of Machne & Murray (2012) <doi:10.1371/journal.pone.0037906>), and here is used as a basis of segment similarity measures. Notably, the time-series processing and clustering functions can also be used as stand-alone tools, independent of segmentation, e.g., for transcriptome data already mapped to genes. / GPL-2	linux-64, osx-64, win-64
r-segmentor3isback	2.0	Performs a fast exact segmentation on data and allows for use of various cost functions. / GPL-2	linux-64, osx-64, win-64
r-segmentr	0.2.0	Given a likelihood provided by the user, this package applies it to a given matrix dataset in order to find change points in the data that maximize the sum of the likelihoods of all the segments. This package provides a handful of algorithms with different time complexities and assumption compromises so the user is able to choose the best one for the problem at hand. The implementation of the segmentation algorithms in this package are based on the paper by Bruno M. de Castro, Florencia Leonardi (2018) <arXiv:1501.01756>. The Berlin weather sample dataset was provided by Deutscher Wetterdienst < https://dwd.de/ >. You can find all the references in the Acknowledgments section of this package’s repository via the URL below. / MIT	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-segmarch	1.2	Implements a segmentation algorithm for multiple change-point detection in high-dimensional GARCH processes. It simultaneously segments GARCH processes by identifying ‘common’ change-points, each of which can be shared by a subset or all of the component time series as a change-point in their within-series and/or cross-sectional correlation structure. / GPL-2	linux-64, osx-64, win-64
r-segregation	0.2.0	Computes entropy-based segregation indices, as developed by Theil (1971) <isbn:978-0471858454>, with a focus on the Mutual Information Index (M) and Theil’s Information Index (H). The M, further described by Mora and Ruiz-Castillo (2011) <doi:10.1111/j.1467-9531.2011.01237.x> and Frankel and Volij (2011) <doi:10.1016/j.jet.2010.10.008>, is a measure of segregation that is highly decomposable. The package provides tools to decompose the index by units and groups (local segregation), and by within and between terms. Includes standard error estimation by bootstrapping. / MIT	noarch
r-seismic	1.0	An implementation of self-exciting point process model for information cascades, which occurs when many people engage in the same acts after observing the actions of others (e.g. post resharings on Facebook or Twitter). It provides functions to estimate the infectiousness of an information cascade and predict its popularity given the observed history. See http://snap.stanford.edu/seismic/ for more information and datasets. / GPL-3	noarch
r-seismicroll	1.1.3	Fast versions of seismic analysis functions that ‘roll’ over a vector of values. See the ‘RcppRoll’ package for alternative versions of basic statistical functions such as rolling mean, median, etc. / GPL-2	linux-64, osx-64, win-64
r-sejong	0.01	Sejong(http://www.sejong.or.kr/) corpus and Hannanum(http://semanticweb.kaist.ac.kr/home/index.php/HanNanum) dictionaries for KoNLP / GPL-3	noarch
r-sel	1.0_2	This package implements a novel method for fitting a bounded probability distribution to quantiles (for example stated by an expert), see Bornkamp and Ickstadt (2009) for details. For this purpose B-splines are used, and the density is obtained by penalized least squares based on a Brier entropy penalty. The package provides methods for fitting the distribution as well as methods for evaluating the underlying density and cdf. In addition methods for plotting the distribution, drawing random numbers and calculating quantiles of the obtained distribution are provided. / GPL-3	linux-64, osx-64, win-64
r-selectapref	0.1.1	Provides indices such as Manly’s alpha, foraging ratio, and Ivlev’s selectivity to allow for analysis of dietary selectivity and preference. Can accommodate multiple experimental designs such as constant prey number of prey depletion. Please contact the package maintainer with any publications making use of this package in an effort to maintain a repository of dietary selections studies. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-selectiongain	2.0.59	Multi-stage selection is practiced in numerous fields of life and social sciences and particularly in breeding. A special characteristic of multi-stage selection is that candidates are evaluated in successive stages with increasing intensity and effort, and only a fraction of the superior candidates is selected and promoted to the next stage. For the optimum design of such selection programs, the selection gain plays a crucial role. It can be calculated by integration of a truncated multivariate normal (MVN) distribution. While mathematical formulas for calculating the selection gain and the variance among selected candidates were developed long time ago, solutions for numerical calculation were not available. This package can also be used for optimizing multi-stage selection programs for a given total budget and different costs of evaluating the candidates in each stage. / GPL-2	noarch
r-selectmeta	1.0.8	Publication bias, the fact that studies identified for inclusion in a meta analysis do not represent all studies on the topic of interest, is commonly recognized as a threat to the validity of the results of a meta analysis. One way to explicitly model publication bias is via selection models or weighted probability distributions. In this package we provide implementations of several parametric and nonparametric weight functions. The novelty in Rufibach (2011) is the proposal of a non-increasing variant of the nonparametric weight function of Dear & Begg (1992). The new approach potentially offers more insight in the selection process than other methods, but is more flexible than parametric approaches. To maximize the log-likelihood function proposed by Dear & Begg (1992) under a monotonicity constraint we use a differential evolution algorithm proposed by Ardia et al (2010a, b) and implemented in Mullen et al (2009). In addition, we offer a method to compute a confidence interval for the overall effect size theta, adjusted for selection bias as well as a function that computes the simulation-based p-value to assess the null hypothesis of no selection as described in Rufibach (2011, Section 6). / GPL-2	noarch
r-selectr	0.4.1	Translates a CSS3 selector into an equivalent XPath expression. This allows us to use CSS selectors when working with the XML package as it can only evaluate XPath expressions. Also provided are convenience functions useful for using CSS selectors on XML nodes. This package is a port of the Python package 'cssselect' (< https://cssselect.readthedocs.io/ >). / BSD_3_clause file LICENCE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-selemix	1.0.1	Detection of outliers and influential errors using a latent variable model. / EUPL	noarch
r-seleniumpipes	0.3.7	The W3C WebDriver specification defines a way for out-of-process programs to remotely instruct the behaviour of web browsers. It is detailed at < https://w3c.github.io/webdriver/webdriver-spec.html >. This package provides an R client implementing the W3C specification. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-selfingtree	0.2	A probability tree allows to compute probabilities of complex events, such as genotype probabilities in intermediate generations of inbreeding through recurrent self-fertilization (selfing). This package implements functionality to compute probability trees for two- and three-marker genotypes in the F2 to F7 selfing generations. The conditional probabilities are derived automatically and in symbolic form. The package also provides functionality to extract and evaluate the relevant probabilities. / BSD_3_clause	noarch
r-semicomprisks	3.3	Hierarchical multistate models are considered to perform the analysis of independent/clustered semi-competing risks data. The package allows to choose the specification for model components from a range of options giving users substantial flexibility, including: accelerated failure time or proportional hazards regression models; parametric or non-parametric specifications for baseline survival functions and cluster-specific random effects distribution; a Markov or semi-Markov specification for terminal event following non-terminal event. While estimation is mainly performed within the Bayesian paradigm, the package also provides the maximum likelihood estimation approach for several parametric models. The package also includes functions for univariate survival analysis as complementary analysis tools. / GPL-2	linux-64, osx-64, win-64
r-semid	0.3.2	Provides routines to check identifiability or non-identifiability of linear structural equation models as described in Drton, Foygel, and Sullivant (2011) <DOI:10.1214/10-AOS859>, Foygel, Draisma, and Drton (2012) <DOI:10.1214/12-AOS1012>, and other works. The routines are based on the graphical representation of structural equation models by a path diagram/mixed graph. / GPL-2	noarch
r-semplr	0.7.0	A powerful, easy to write and easy to modify syntax for specifying and estimating Partial Least Squares (PLS) path models allowing for the latest estimation methods for Consistent PLS as per Dijkstra & Henseler (2015, MISQ 39(2): 297-316), adjusted interactions as per Henseler & Chin (2010) <doi:10.1080/10705510903439003> and bootstrapping utilizing parallel processing as per Hair et al. (2017, ISBN:978-1483377445). / GPL-3	noarch
r-semipar	1.0_4	Functions for semiparametric regression analysis, to complement the book: Ruppert, D., Wand, M.P. and Carroll, R.J. (2003). Semiparametric Regression. Cambridge University Press. / GPL-2	noarch
r-semmodcomp	1.0	Conduct tests of difference in fit for mean and covariance structure models as in structural equation modeling (SEM) / GPL-3	noarch
r-semnetdictionaries	0.1.3	Implements dictionaries that can be used in the ‘SemNetCleaner’ package. Also includes several functions aimed at facilitating the text cleaning analysis in the ‘SemNetCleaner’ package. This package is designed to integrate and update word lists and dictionaries based on each user’s individual needs by allowing users to store and save their own dictionaries. Dictionaries can be added to the ‘SemNetDictionaries’ package by submitting user-defined dictionaries to < https://github.com/AlexChristensen/SemNetDictionaries >. / GPL (>= 3.0)	noarch
r-sempls	1.0_10	Fits structural equation models using partial least squares (PLS). The PLS approach is referred to as ‘soft-modeling’ technique requiring no distributional assumptions on the observed data. / GPL-2	noarch
r-sempower	1.0.0	Provides a-priori, post-hoc, and compromise power-analyses for structural equation models (SEM). Moshagen & Erdfelder (2016) <doi:10.1080/10705511.2014.950896>. / LGPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-semver	0.2.0	Tools and functions for parsing, rendering and operating on semantic version strings. Semantic versioning is a simple set of rules and requirements that dictate how version numbers are assigned and incremented as outlined at < http://semver.org >. / MIT	linux-64, osx-64, win-64
r-sendmailr	1.2_1	Package contains a simple SMTP client which provides a portable solution for sending email, including attachment, from within R. / GPL-2	noarch
r-sensemakr	0.1.2	Implements a suite of sensitivity analysis tools that extends the traditional omitted variable bias framework and makes it easier to understand the impact of omitted variables in regression models, as discussed in Cinelli and Hazlett (2018) < https://www.researchgate.net/publication/322509816_Making_Sense_of_Sensitivity_Extending_Omitted_Variable_Bias >. / GPL-3	noarch
r-sensibo.sky	1.0.0	Provides an interface to the ‘Sensibo Sky’ API which allows to remotely control non-smart air conditioning units. See < https://sensibo.com > for more informations. / MIT	noarch
r-sensitivity2x2xk	1.01	Performs exact or approximate adaptive or nonadaptive Cochran-Mantel-Haenszel-Birch tests and sensitivity analyses for one or two 2x2xk tables in observational studies. / GPL-2	noarch
r-sensitivitycasecontrol	2.1	This package performs sensitivity analysis for case-control studies in which some cases may meet a more narrow definition of being a case compared to other cases which only meet a broad definition. The sensitivity analyses are described in Small, Cheng, Halloran and Rosenbaum (2013, Case Definition and Sensitivity Analysis, Journal of the American Statistical Association, 1457-1468). The functions sens.analysis.mh and sens.analysis.aberrant.rank provide sensitivity analyses based on the Mantel-Haenszel test statistic and aberrant rank test statistic as described in Rosenbaum (1991, Sensitivity Analysis for Matched Case Control Studies, Biometrics); see also Section 1 of Small et al. The function adaptive.case.test provides adaptive inferences as described in Section 5 of Small et al. The function adaptive.noether.brown provides a sensitivity analysis for a matched cohort study based on an adaptive test. The other functions in the package are internal functions. / GPL-2	noarch
r-sensitivityfull	1.5.6	Sensitivity to unmeasured biases in an observational study that is a full match. Function senfm() performs tests and function senfmCI() creates confidence intervals. The method uses Huber’s M-statistics, including least squares, and is described in Rosenbaum (2007, Biometrics) <DOI:10.1111/j.1541-0420.2006.00717.x>. / GPL-2	noarch
r-sensitivitymult	1.0.2	Sensitivity analysis for multiple outcomes in observational studies. For instance, all linear combinations of several outcomes may be explored using Scheffe projections in the comparison() function; see Rosenbaum (2016, Annals of Applied Statistics) <doi:10.1214/16-AOAS942>. Alternatively, attention may focus on a few principal components in the principal() function. The package includes parallel methods for individual outcomes, including tests in the senm() function and confidence intervals in the senmCI() function. / GPL-2	noarch
r-sensitivitymv	1.4.3	The package performs a sensitivity analysis in an observational study using an M-statistic, for instance, the mean. The main function in the package is senmv(), but amplify() and truncatedP() are also useful. The method is developed in Rosenbaum Biometrics, 2007, 63, 456-464, <doi:10.1111/j.1541-0420.2006.00717.x>. / GPL-2	noarch
r-sensitivitymw	1.1	Sensitivity analysis analysis in matched observational studies with multiple controls using weighted M-statistics to increase design sensitivity. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sensitivypstrat	1.0.6	This package provides functions to perform principal stratification sensitivity analyses on datasets. / GPL-3	linux-64, osx-64, win-64
r-sensmediation	0.3.0	We implement functions to estimate and perform sensitivity analysis to unobserved confounding of direct and indirect effects introduced in Lindmark, de Luna and Eriksson (2018) <doi:10.1002/sim.7620>. The estimation and sensitivity analysis are parametric, based on probit and/or linear regression models. Sensitivity analysis is implemented for unobserved confounding of the exposure-mediator, mediator-outcome and exposure-outcome relationships. / GPL-2	noarch
r-sensory	1.1	Contains the function CUUimpute() which performs model-based clustering and imputation simultaneously. / GPL-2	noarch
r-sensr	1.5.1	Provides methods for sensory discrimination methods; duotrio, tetrad, triangle, 2-AFC, 3-AFC, A-not A, same-different, 2-AC and degree-of-difference. This enables the calculation of d-primes, standard errors of d-primes, sample size and power computations, and comparisons of different d-primes. Methods for profile likelihood confidence intervals and plotting are included. / GPL-2 GPL-3	noarch
r-sensrivastava	2015.02.1	Collection of datasets from Sen & Srivastava: Regression Analysis, Theory, Methods and Applications, Springer. Sources for individual data files are more fully documented in the book. / GPL-2	noarch
r-senstrat	1.0.3	Sensitivity analysis in unmatched observational studies, with or without strata. The main functions are sen2sample() and senstrat(). See Rosenbaum, P. R. and Krieger, A. M. (1990), JASA, 85, 493-498, <doi:10.1080/01621459.1990.10476226> and Gastwirth, Krieger and Rosenbaum (2000), JRSS-B, 62, 545-555 <doi:10.1111/1467-9868.00249> . / GPL-2	noarch
r-separate	0.2.1	It combines maximum likelihood estimation of the parameters of matrix and 3rd-order tensor normal distributions with unstructured factor variance-covariance matrices, two procedures, and unbiased modified likelihood ratio testing of simple and double separability for variance-covariance structures, two procedures. / MIT	noarch
r-separationplot	1.1	Functions to generate separation plots for evaluation of model fit. / Artistic-2.0	noarch
r-seqalloc	1.0	Potential randomization schemes are prospectively evaluated when units are assigned to treatment arms upon entry into the experiment. The schemes are evaluated for balance on covariates and on predictability (i.e., how well could a site worker guess the treatment of the next unit enrolled). / GPL-2	noarch
r-seqcbcs	1.2.1	This is a method for DNA Copy Number Profiling using Next-Generation Sequencing. It has new model and test statistics based on non-homogeneous Poisson Processes with change point models. It uses an adaptation of Circular Binary Segmentation. Also included are methods for point-wise Bayesian Confidence Interval and model selection method for the change-point model. A case and a control sample reads (normal and tumor) are required. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-seqdesign	1.2	A modification of the preventive vaccine efficacy trial design of Gilbert, Grove et al. (2011, Statistical Communications in Infectious Diseases) is implemented, with application generally to individual-randomized clinical trials with multiple active treatment groups and a shared control group, and a study endpoint that is a time-to-event endpoint subject to right-censoring. The design accounts for the issues that the efficacy of the treatment/vaccine groups may take time to accrue while the multiple treatment administrations/vaccinations are given; there is interest in assessing the durability of treatment efficacy over time; and group sequential monitoring of each treatment group for potential harm, non-efficacy/efficacy futility, and high efficacy is warranted. The design divides the trial into two stages of time periods, where each treatment is first evaluated for efficacy in the first stage of follow-up, and, if and only if it shows significant treatment efficacy in stage one, it is evaluated for longer-term durability of efficacy in stage two. The package produces plots and tables describing operating characteristics of a specified design including an unconditional power for intention-to-treat and per-protocol/as-treated analyses; trial duration; probabilities of the different possible trial monitoring outcomes (e.g., stopping early for non-efficacy); unconditional power for comparing treatment efficacies; and distributions of numbers of endpoint events occurring after the treatments/vaccinations are given, useful as input parameters for the design of studies of the association of biomarkers with a clinical outcome (surrogate endpoint problem). The code can be used for a single active treatment versus control design and for a single-stage design. / GPL-2	noarch
r-seqicp	1.1	Contains an implementation of invariant causal prediction for sequential data. The main function in the package is 'seqICP', which performs linear sequential invariant causal prediction and has guaranteed type I error control. For non-linear dependencies the package also contains a non-linear method 'seqICPnl', which allows to input any regression procedure and performs tests based on a permutation approach that is only approximately correct. In order to test whether an individual set S is invariant the package contains the subroutines 'seqICP.s' and 'seqICPnl.s' corresponding to the respective main methods. / GPL-3	noarch
r-seqmade	1.0	A network module-based generalized linear model for differential expression analysis with the count-based sequence data from RNA-Seq. / GPL-2	noarch
r-seqmeta	1.6.7	Computes necessary information to meta analyze region-based tests for rare genetic variants (e.g. SKAT, T1) in individual studies, and performs meta analysis. / GPL-2	linux-64, osx-64, win-64
r-seqminer	7.1	Integrate sequencing data (Variant call format, e.g. VCF or BCF) or meta-analysis results in R. This package can help you (1) read VCF/BCF/BGEN files by chromosomal ranges (e.g. 1:100-200); (2) read RareMETAL summary statistics files; (3) read tables from a tabix-indexed files; (4) annotate VCF/BCF files; (5) create customized workflow based on Makefile. / GPL-3	linux-64, osx-64, win-64
r-seqmon	2.3	S4 class object for creating and managing group sequential designs. It calculates the efficacy and futility boundaries at each look. It allows modifying the design and tracking the design update history. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-seqrfnp	1.0.1	This package includes functions for handling DNA sequences, especially simulated RFLP and TRFLP pattern based on selected restriction enzyme and DNA sequences. / GPL-2	noarch
r-seqtest	0.1_0	Sequential triangular test for the arithmetic mean in one- and two- samples, proportions in one- and two-samples, and the Pearson's correlation coefficient. / GPL-3	noarch
r-sequences	0.5.9	Educational package used in R courses to illustrate object-oriented programming and package development. Using biological sequences (DNA and RNA) as a working example. / GPL-3	linux-64, osx-64, win-64
r-sequential	3.0.1	Functions to calculate exact critical values, statistical power, expected time to signal, and required sample sizes for performing exact sequential analysis. All these calculations can be done for either Poisson or binomial data, for continuous or group sequential analyses, and for different types of rejection boundaries. In case of group sequential analyses, the group sizes do not have to be specified in advance and the alpha spending can be arbitrarily settled. / GPL-2	noarch
r-sequoia	1.3.3	Fast multi-generational pedigree inference from incomplete data on hundreds of SNPs, including parentage assignment and sibship clustering. See Huisman (2017) (DOI:10.1111/1755-0998.12665, citation('sequoia')) for more information. / GPL-2	linux-64, osx-64, win-64
r-serial	2.1.4	Enables reading and writing binary and ASCII data to RS232/RS422/RS485 or any other virtual serial interfaces of the computer. / GPL-2	noarch
r-serieslcb	0.4.0	Calculate and compare lower confidence bounds for binomial series system reliability. The R 'shiny' application, launched by the function launch_app(), weaves together a workflow of customized simulations and delta coverage calculations to output recommended lower confidence bound methods. / GPL-3	noarch
r-seroincidence	2.0.0	Translates antibody levels measured in a (cross-sectional) population sample into an estimate of the frequency with which seroconversions (infections) occur in the sampled population. / GPL-3	noarch
r-servr	0.15	Start an HTTP server in R to serve static files, or dynamic documents that can be converted to HTML files (e.g., R Markdown) under a given directory. / GPL-3	noarch
r-sesem	1.0.2	Structural equation modeling is a powerful statistical approach for the testing of networks of direct and indirect theoretical causal relationships in complex data sets with inter-correlated dependent and independent variables. Here we implement a simple method for spatially explicit structural equation modeling based on the analysis of variance co-variance matrices calculated across a range of lag distances. This method provides readily interpreted plots of the change in path coefficients across scale. / GPL-2	noarch
r-session	1.0.3	Utility functions for interacting with R processes from external programs. This package includes functions to save and restore session information (including loaded packages, and attached data objects), as well as functions to evaluate strings containing R commands and return the printed results or an execution transcript. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sessioninfo	1.1.1	Query and print information about the current R session. It is similar to 'utils::sessionInfo()', but includes more information about packages, and where they were installed from. / GPL-2	noarch
r-setpath	1.0	Tests gene expression data from a biological pathway for biologically meaningful differences in the eigenstructure between two classes. Specifically, it tests the null hypothesis that the two classes' leading eigenvalues and sums of eigenvalues are equal. A pathway's leading eigenvalue arguably represents the total variability due to variability in pathway activity, while the sum of all its eigenvalues represents the variability due to pathway activity and to other, unregulated causes. Implementation of the method described in Danaher (2015), Covariance-based analyses of biological pathways. / GPL-2	noarch
r-setrank	1.1.0	Implements an algorithm to conduct advanced gene set enrichment analysis on the results of genomics experiments. / GPL-3	noarch
r-setrng	2013.9	SetRNG provides utilities to help set and record the setting of the seed and the uniform and normal generators used when a random experiment is run. The utilities can be used in other functions that do random experiments to simplify recording and/or setting all the necessary information for reproducibility. See the vignette and reference manual for examples. / GPL-2	noarch
r-sets	1.0_1	Data structures and basic operations for ordinary sets, generalizations such as fuzzy sets, multisets, and fuzzy multisets, customizable sets, and intervals. / GPL-2	linux-64, osx-64, win-64
r-setter	0.0_1	Mutators to set attributes of variables, that work well in a pipe (much like stats::setNames()). / Unlimited	noarch
r-settest	0.2.0	It provides cumulative distribution function (CDF), quantile, p-value, statistical power calculator and random number generator for a collection of group-testing procedures, including the Higher Criticism tests, the one-sided Kolmogorov-Smirnov tests, the one-sided Berk-Jones tests, the one-sided phi-divergence tests, etc. The input are a group of p-values. The null hypothesis is that they are i.i.d. Uniform(0,1). In the context of signal detection, the null hypothesis means no signals. In the context of the goodness-of-fit testing, which contrasts a group of i.i.d. random variables to a given continuous distribution, the input p-values can be obtained by the CDF transformation. The null hypothesis means that these random variables follow the given distribution. For reference, see Hong Zhang, Jiashun Jin and Zheyang Wu. Distributions and Statistical Power of Optimal Signal-Detection Methods In Finite Cases, submitted. / GPL-2	noarch
r-settings	0.2.4	Provides option settings management that goes beyond R's default 'options' function. With this package, users can define their own option settings manager holding option names, default values and (if so desired) ranges or sets of allowed option values that will be automatically checked. Settings can then be retrieved, altered and reset to defaults with ease. For R programmers and package developers it offers cloning and merging functionality which allows for conveniently defining global and local options, possibly in a multilevel options hierarchy. See the package vignette for some examples concerning functions, S4 classes, and reference classes. There are convenience functions to reset par() and options() to their 'factory defaults'. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-severity</code>	2.0	This package contains functions for calculating severity and generating severity curves. Specifically, the simple case of the one-parameter Normal distribution (i.e., with known variance) is considered. / GPL-2	noarch
<code>r-sf</code>	0.6_3	Support for simple features, a standardized way to encode spatial vector data. Binds to 'GDAL' for reading and writing data, to 'GEOS' for geometrical operations, and to 'PROJ' for projection conversions and datum transformations. / GPL-2 MIT file LICENSE	linux-32, linux-64, osx-64, win-64
<code>r-sfa</code>	1.0_1	Stochastic Frontier Analysis introduced by Aigner, Lovell and Schmidt (1976) and Battese and Coelli (1992, 1995). / GPL-2	noarch
<code>r-sfinx</code>	1.7.99	The straightforward filtering index (SFINX) identifies true positive protein interactions in a fast, user-friendly, and highly accurate way. It is not only useful for the filtering of affinity purification - mass spectrometry (AP-MS) data, but also for similar types of data resulting from other co-complex interactomics technologies, such as TAP-MS, Virotrap and BioID. SFINX can also be used via the website interface at < http://sfinx.ugent.be >. / Apache License 2.0	noarch
<code>r-sfs</code>	0.1.4	An implementation of the Similarity-First Search algorithm (SFS), a combinatorial algorithm which can be used to solve the seriation problem and to recognize some structured weighted graphs. The SFS algorithm represents a generalization to weighted graphs of the graph search algorithm Lexicographic Breadth-First Search (Lex-BFS), a variant of Breadth-First Search. The SFS algorithm reduces to Lex-BFS when applied to binary matrices (or, equivalently, unweighted graphs). Hence this library can be also considered for Lex-BFS applications such as recognition of graph classes like chordal or unit interval graphs. In fact, the SFS seriation algorithm implemented in this package is a multisweep algorithm, which consists in repeating a finite number of SFS iterations (at most n sweeps for a matrix of size n). If the data matrix has a Robinsonian structure, then the ranking returned by the multistep SFS algorithm is a Robinson ordering of the input matrix. Otherwise the algorithm can be used as a heuristic to return a ranking partially satisfying the Robinson property. / GPL-3	linux-64, osx-64, win-64
<code>r-sfsmisc</code>	1.1_3	Useful utilities ['goodies'] from Seminar fuer Statistik ETH Zurich, some of which were ported from S-plus in the 1990's. For graphics, have pretty (Log-scale) axes, an enhanced Tukey-Anscombe plot, combining histogram and boxplot, 2d-residual plots, a 'tachoPlot()', pretty arrows, etc. For robustness, have a robust F test and robust range(). For system support, notably on Linux, provides 'Sys.*()' functions with more access to system and CPU information. Finally, miscellaneous utilities such as simple efficient prime numbers, integer codes, Duplicated(), toLatex.numeric() and is.whole(). / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sgb	1.0	Main properties and regression procedures using a generalization of the Dirichlet distribution called Simplicial Generalized Beta distribution. It is a new distribution on the simplex (i.e. on the space of compositions or positive vectors with sum of components equal to 1). The Dirichlet distribution can be constructed from a random vector of independent Gamma variables divided by their sum. The SGB follows the same construction with generalized Gamma instead of Gamma variables. The Dirichlet exponents are supplemented by an overall shape parameter and a vector of scales. The scale vector is itself a composition and can be modeled with auxiliary variables through a log-ratio transformation. Graf, M. (2017, ISBN: 978-84-947240-0-8). See also the vignette enclosed in the package. / GPL-2	noarch
r-sgee	0.6_0	Stagewise techniques implemented with Generalized Estimating Equations to handle individual, group, bi-level, and interaction selection. Stagewise approaches start with an empty model and slowly build the model over several iterations, which yields a ‘path’ of candidate models from which model selection can be performed. This ‘slow brewing’ approach gives stagewise techniques a unique flexibility that allows simple incorporation of Generalized Estimating Equations; see Vaughan, G., Aseltine, R., Chen, K., Yan, J., (2017) <doi:10.1111/biom.12669> for details. / GPL-3	noarch
r-sgeostat	1.0_2	An Object-oriented Framework for Geostatistical Modeling in S containing functions for variogram estimation, variogram fitting and kriging as well as some plot functions. Written entirely in S, therefore works only for small data sets in acceptable computing time. / GPL-2	linux-64, osx-64, win-64
r-sgl	1.2	Fit a regularized generalized linear model via penalized maximum likelihood. The model is fit for a path of values of the penalty parameter. Fits linear, logistic and Cox models. / GPL-3	linux-64, osx-64, win-64
r-sglasso	1.2.3	RCON(V, E) models are a kind of restriction of the Gaussian Graphical Models defined by a set of equality constraints on the entries of the concentration matrix. ‘sglasso’ package implements the structured graphical lasso (sglasso) estimator proposed in Abbruzzo et al. (2014) for the weighted l1-penalized RCON(V, E) model. Two cyclic coordinate algorithms are implemented to compute the sglasso estimator, i.e. a cyclic coordinate minimization (CCM) and a cyclic coordinate descent (CCD) algorithm. / GPL-2	linux-64, osx-64, win-64
r-sgloptim	1.3.8	Fast generic solver for sparse group lasso optimization problems. The loss (objective) function must be defined in a C module. The optimization problem is solved using a coordinate gradient descent algorithm. Convergence of the algorithm is established (see reference) and the algorithm is applicable to a broad class of loss functions. Use of parallel computing for cross validation and subsampling is supported through the ‘foreach’ and ‘doParallel’ packages. Development version is on GitHub, please report package issues on GitHub. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sgmcmc	0.2.4	Provides functions that performs popular stochastic gradient Markov chain Monte Carlo (SGMCMC) methods on user specified models. The required gradients are automatically calculated using ‘TensorFlow’ < https://www.tensorflow.org/ >, an efficient library for numerical computation. This means only the log likelihood and log prior functions need to be specified. The methods implemented include stochastic gradient Langevin dynamics (SGLD), stochastic gradient Hamiltonian Monte Carlo (SGHMC), stochastic gradient Nose-Hoover thermostat (SGNHT) and their respective control variate versions for increased efficiency. References: M. Welling, Y. W. Teh (2011) < http://www.icml-2011.org/papers/398_icmlpaper.pdf >; T. Chen, E. B. Fox, C. E. Guestrin (2014) <arXiv:1402.4102>; N. Ding, Y. Fang, R. Babbush, C. Chen, R. D. Skeel, H. Neven (2014) < https://papers.nips.cc/paper/5592-bayesian-sampling-using-stochastic-gradient-thermostats >; J. Baker, P. Fearnhead, E. B. Fox, C. Nemeth (2017) <arXiv:1706.05439>. / GPL-3	noarch
r-sgpdata	21.0	Data sets utilized by the ‘SGP’ package as exemplars for users to conduct their own student growth percentiles (SGP) analyses. / GPL-3	noarch
r-sgr	1.3	The package for Sample Generation by Replacement simulations (SGR; Lombardi & Pastore, 2014; Pastore & Lombardi, 2014). The package can be used to perform fake data analysis according to the sample generation by replacement approach. It includes functions for making simple inferences about discrete/ordinal fake data. The package allows to study the implications of fake data for empirical results. / GPL-2	noarch
r-sgrsea	0.1	Provides functions to implement sgRSEA (single-guide RNA Set Enrichment Analysis), which is a robust test for identification of essential genes from genetic screening data using CRISPR (clustered regularly interspaced short palindromic repeats) and Cas9 (CRISPR-associated nuclease 9) system. / GPL-2	noarch
r-shades	1.4.0	Functions for easily manipulating colours, creating colour scales and calculating colour distances. / BSD_3_clause	noarch
r-shape	1.4.4	Functions for plotting graphical shapes such as ellipses, circles, cylinders, arrows, ... / GPL-3	noarch
r-shapechange	1.4	In a scatterplot where the response variable is Gaussian, Poisson or binomial, we consider the case in which the mean function is smooth with a change-point, which is a mode, an inflection point or a jump point. The main routine estimates the mean curve and the change-point as well using shape-restricted B-splines. An optional subroutine delivering a bootstrap confidence interval for the change-point is incorporated in the main routine. / GPL-2	noarch
r-shapefiles	0.7	Functions to read and write ESRI shapefiles / GPL-3	noarch
r-sharpdata	1.2	Functions and data sets inspired by data sharpening - data perturbation to achieve improved performance in nonparametric estimation, as described in Choi, E., Hall, P. and Rousson, V. (2000) <doi:10.1214/aos/1015957396>. Capabilities for enhanced local linear regression function and derivative estimation are included, as well as an asymptotically correct iterated data sharpening estimator for any degree of local polynomial regression estimation. A cross-validation-based bandwidth selector is included which, in concert with the iterated sharpener, will often provide superior performance, according to a median integrated squared error criterion. Sample data sets are provided to illustrate function usage. / Unlimited	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-sharpr2</code>	1.1.1.0	An algorithm for identifying high-resolution driver elements for datasets from a high-definition reporter assay library. Xincheng Wang, Liang He, Sarah Goggin, Alham Saadat, Li Wang, Melina Claussnitzer, Manolis Kellis (2017) <doi:10.1101/193136>. / GPL-2	noarch
<code>r-shiftr</code>	1.5	Fast enrichment analysis for locally correlated statistics via circular permutations. The analysis can be performed at multiple significance thresholds for both primary and auxiliary data sets with efficient correction for multiple testing. / LGPL-3	linux-64, osx-64, win-64
<code>r-shiftsharese</code>	1.0.0	Provides confidence intervals in least-squares regressions when the variable of interest has a shift-share structure, and in instrumental variables regressions when the instrument has a shift-share structure. The confidence intervals implement the AKM and AKM0 methods developed in Adão, Kolesár, and Morales (2019) <doi:10.1093/qje/qjz025>. / GPL-3	noarch
<code>r-shiny</code>	1.3.2	Makes it incredibly easy to build interactive web applications with R. Automatic reactive binding between inputs and outputs and extensive prebuilt widgets make it possible to build beautiful, responsive, and powerful applications with minimal effort. / GPL-3 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-shiny.i18n</code>	0.1.0	It provides easy internationalization of Shiny applications. It can be used as standalone translation package to translate reports, interactive visualizations or graphical elements as well. / MIT	noarch
<code>r-shiny.router</code>	0.1.1	The minimal router for your Shiny apps. It allows you to create dynamic web applications with real-time user interface and easily share URLs to pages within your Shiny apps. / MIT	noarch
<code>r-shiny.semantic</code>	0.2.1	Creating a great user interface for your Shiny apps can be a hassle, especially if you want to work purely in R and don't want to use, for instance HTML templates. This package adds support for a powerful UI library Semantic UI - < http://semantic-ui.com/ >. It also supports universal UI input binding that works with various DOM elements. / MIT	noarch
<code>r-shinyace</code>	0.4.0	Ace editor bindings to enable a rich text editing environment within Shiny. / MIT	noarch
<code>r-shinyiframe</code>	1.0.1	Make R data available in Web-based virtual reality experiences for immersive, cross-platform data visualizations. Includes the 'gg-iframe' JavaScript package for a Grammar of Graphics declarative HTML syntax to create 3-dimensional data visualizations with 'Mozilla A-Frame' < https://aframe.io/ >. / AGPL-3	noarch
<code>r-shinyalert</code>	1.0	Easily create pretty popup messages (modals) in 'Shiny'. A modal can contain text, images, OK/Cancel buttons, an input to get a response from the user, and many more customizable options. / MIT	noarch
<code>r-shinyanimate</code>	0.3.0	An extension of 'animate.css' that allows user to easily add animations to any UI element in 'shiny' app using the elements id. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-shinybootstrap2	0.2.1	Provides Bootstrap 2 web components for use with the Shiny package. With versions of Shiny prior to 0.11, these Bootstrap 2 components were included as part of the package. Later versions of Shiny include Bootstrap 3, so the Bootstrap 2 components have been moved into this package for those uses who rely on features specific to Bootstrap 2. / GPL-3	noarch
r-shinybs	0.61	Adds additional Twitter Bootstrap components to Shiny. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-shinybusy	0.1.3	Add a global indicator (spinner, progress bar, gif) in your ‘shiny’ applications to show the user that the server is busy. / GPL-3	noarch
r-shinycssloaders	0.2.0	Create a lightweight Shiny wrapper for the css-loaders created by Luke Hass < https://github.com/lukehaas/css-loaders >. Wrapping a Shiny output will automatically show a loader when the output is (re)calculating. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-shinycustomloader	0.9.0	A custom css/html or gif/image file for the loading screen in R ‘shiny’. It also can use the marquee to have custom text loading screen. / GPL-3	noarch
r-shinydashboard	0.7.1	Create dashboards with ‘Shiny’. This package provides a theme on top of ‘Shiny’, making it easy to create attractive dashboards. / GPL (>= 2) file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-shinydashboardplus	0.7.0	Extend ‘shinydashboard’ with ‘AdminLTE2’ components. ‘AdminLTE2’ is a free ‘Bootstrap 3’ dashboard template available at < https://adminlte.io >. Customize boxes, add timelines and a lot more. / GPL-2	noarch
r-shinydnd	0.1.0	Add functionality to create drag and drop div elements in shiny. / GPL-3	noarch
r-shinyeffects	0.1.0	Add fancy CSS effects to your ‘shinydashboards’ or ‘shiny’ apps. 100% compatible with ‘shinydashboardPlus’ and ‘bs4Dash’. / GPL-2	noarch
r-shinyfeedback	0.1.0	Easily display user feedback next to Shiny inputs. The feedback message is displayed when the feedback condition evaluates to TRUE. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-shinyglide	0.1.1	Insert Glide JavaScript component into Shiny applications for carousel or assistant-like user interfaces. / GPL-3	noarch
r-shinyhelper	0.3.1	Creates a lightweight way to add markdown helpfiles to ‘shiny’ apps, using modal dialog boxes, with no need to observe each help button separately. / GPL-3	noarch
r-shinyjq	0.3.2	An extension to shiny that brings interactions and animation effects from ‘jQuery UI’ library. / MIT	noarch
r-shinyjs	1.0	Perform common useful JavaScript operations in Shiny apps that will greatly improve your apps without having to know any JavaScript. Examples include: hiding an element, disabling an input, resetting an input back to its original value, delaying code execution by a few seconds, and many more useful functions for both the end user and the developer. ‘shinyjs’ can also be used to easily call your own custom JavaScript functions from R. / AGPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-shinylp	1.1.2	Provides functions that wrap HTML Bootstrap components code to enable the design and layout of informative landing home pages for Shiny applications. This can lead to a better user experience for the users and writing less HTML for the developer. / MIT	noarch
r-shinymaterial	0.5.5	Allows shiny developers to incorporate UI elements based on Google’s Material design. See < https://material.io/guidelines/ > for more information. / GPL-3	noarch
r-shinymatrix	0.2.0	Implements a custom matrix input field. / MIT	noarch
r-shinyshortcut	0.1.0	Provides function shinyShortcut() that, when given the base directory of a shiny application, will produce an executable file that runs the shiny app directly in the user’s default browser. Tested on both windows and unix machines. Inspired by and borrowing from < http://www.mango-solutions.com/wp/2017/03/shiny-based-tablet-or-desktop-app/ >. / GPL-3	noarch
r-shinysky	2.0.0	A set of Shiny UI components includings alerts and styled buttons / MIT	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-shinythemes	1.1.2	Themes for use with Shiny. Includes several Bootstrap themes from http://bootswatch.com/ , which are packaged for use with Shiny applications. / GPL-3 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-shinytime	1.0.1	Provides a time input widget for Shiny. This widget allows intuitive time input in the '[hh]:[mm]:[ss]' or '[hh]:[mm]' (24H) format by using a separate numeric input for each time component. The interface with R uses date-time objects. See the project page for more information and examples. / GPL-3	noarch
r-shinytoastr	2.1.1	Browser notifications in 'Shiny' apps, using 'toastr': https://github.com/CodeSeven/toastr#readme . / MIT	noarch
r-shinytree	0.2.7	Exposes bindings to jsTree – a JavaScript library that supports interactive trees – to enable a rich, editable trees in Shiny. / MIT	noarch
r-shinywidgets	0.4.9	Collection of custom input controls and user interface components for 'Shiny' applications. Give your applications a unique and colorful style ! / GPL-3	noarch
r-ship	1.0.2	The SHIP-package allows the estimation of various types of shrinkage covariance matrices. These types differ in terms of the so-called covariance target (to be chosen by the user), the highly structured matrix which the standard unbiased sample covariance matrix is shrunk towards and which optionally incorporates prior biological knowledge extracted from the database KEGG. The shrinkage intensity is obtained via an analytical procedure. / GPL-2	noarch
r-shipunov	1.2	A collection of functions for data manipulation, plotting and statistical computing, to use separately or with the book Visual Statistics. Use R!: Shipunov (2019) http://ashipunov.info/shipunov/software/r/r-en.htm . Most useful functions are probably Bclust(), Jclust() and BootA() which bootstrap hierarchical clustering; Recode...() which multiple recode in a fast, flexible and simple way; Misclass() which outputs confusion matrix even if classes are not concerted; Overlap() which calculates overlaps of convex hulls from any projection; and Pleiad() which is fast and flexible correlogram. In fact, there are much more useful functions, please see documentation. / GPL-2	noarch
r-shopifyr	1.0.0	An interface to the Admin API of the E-commerce service Shopify, (https://help.shopify.com/en/api/reference). / GPL-3	noarch
r-shotgroups	0.7.5	Analyzes shooting data with respect to group shape, precision, and accuracy. This includes graphical methods, descriptive statistics, and inference tests using standard, but also non-parametric and robust statistical methods. Implements distributions for radial error in bivariate normal variables. Works with files exported by 'OnTarget PC/TDS', 'Silver Mountain' e-target, 'Shot-Marker' e-target, or 'Taran', as well as with custom data files in text format. Supports inference from range statistics like extreme spread. Includes a set of web-based graphical user interfaces. / GPL-2	noarch
r-showimage	1.0.0	Sometimes it is handy to be able to view an image file on an 'R' graphics device. This package just does that. Currently it supports 'PNG' files. / GPL-2 GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-shp2graph	0.5	Functions for converting network data from a <code>SpatialLinesDataFrame</code> object to an 'igraph'-Class object. / GPL-2	linux-64, osx-64, win-64
r-shrinkcovmat	1.4.0	Provides nonparametric Steinian shrinkage estimators of the covariance matrix that are suitable in high dimensional settings, that is when the number of variables is larger than the sample size. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-shuffle	1.0.1	Implementation of the shuffle estimator, a non-parametric estimator for signal and noise variance under mild noise correlations. / GPL (>= 2.0)	noarch
r-shutterstock	0.1.0	Access 'Shutterstock' API from R. The 'Shutterstock' API presents access to search, view, license and download the media and information from the 'Shutterstock's library < https://api-reference.shutterstock.com/ >. / MIT	noarch
r-si	0.2.0	An implementation of four stochastic methods of integrating in R, including: 1. Stochastic Point Method (or Monte Carlo Method); 2. Mean Value Method; 3. Important Sampling Method; 4. Stratified Sampling Method. It can be used to estimate one-dimension or multi-dimension integration by Monte Carlo methods. And the estimated variance (precision) is given. Reference: Caflisch, R. E. (1998) <doi:10.1017/S0962492900002804>. / GPL-3	noarch
r-siebanxicor	1.0.0	Allows to retrieve time series of all indicators available in the Bank of Mexico's Economic Information System (< http://www.banxico.org.mx/SieInternet/ >). / MIT	noarch
r-sier	0.1.0	Methods for regression with high-dimensional predictors and univariate or multivariate response variables. It considers the decomposition of the coefficient matrix that leads to the best approximation to the signal part in the response given any rank, and estimates the decomposition by solving a penalized generalized eigenvalue problem followed by a least squares procedure. Ruiyan Luo and Xin Qi (2017) <doi:10.1016/j.jmva.2016.09.005>. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sieveph	1.0.0	Implements semiparametric estimation and testing procedures for a continuous, possibly multivariate, mark-specific hazard ratio (treatment/placebo) of an event of interest in a randomized treatment efficacy trial with a time-to-event endpoint, as described in Juraska M and Gilbert PB (2013), Mark-specific hazard ratio model with multivariate continuous marks: an application to vaccine efficacy. <i>Biometrics</i> 69(2):328-337, and in Juraska M and Gilbert PB (2015), Mark-specific hazard ratio model with missing multivariate marks. <i>Lifetime Data Analysis</i> 22(4): 606-25. The former considers continuous multivariate marks fully observed in all subjects who experience the event of interest, whereas the latter extends the previous work to allow multivariate marks that are subject to missingness-at-random. For models with missing marks, two estimators are implemented based on (i) inverse probability weighting (IPW) of complete cases, and (ii) augmentation of the IPW estimating functions by leveraging correlations between the mark and auxiliary data to ‘impute’ the expected profile score vectors for subjects with missing marks. The augmented IPW estimator is doubly robust and recommended for use with incomplete mark data. The methods make two key assumptions: (i) the time-to-event is assumed to be conditionally independent of the mark given treatment, and (ii) the weight function in the semiparametric density ratio/biased sampling model is assumed to be exponential. Diagnostic testing procedures for evaluating validity of both assumptions are implemented. Summary and plotting functions are provided for estimation and inferential results. / GPL-2	noarch
r-sievetest	1.2.3	Functions for making particle-size analysis. Sieve tests are widely used to obtain particle-size distribution of powders or granular materials. / GPL-2	noarch
r-sig	0.0_5	Print function signatures and find overly complicated code. / Unlimited	noarch
r-sigclust	1.1.0	SigClust is a statistical method for testing the significance of clustering results. SigClust can be applied to assess the statistical significance of splitting a data set into two clusters. For more than two clusters, SigClust can be used iteratively. / GPL-2	noarch
r-sightabilitymodel	1.3	Uses logistic regression to model the probability of detection as a function of covariates. This model is then used with observational survey data to estimate population size, while accounting for uncertain detection. See Steinhorst and Samuel (1989). / GPL-2	noarch
r-sigmanet	1.1.0	Create interactive graph visualizations using ‘Sigma.js’ < http://sigmaj.js.org/ >. This package is meant to be used in conjunction with ‘igraph’, replacing the (somewhat underwhelming) plotting features of the package. The idea is to quickly render graphs, regardless of their size, in a way that allows for easy, iterative modification of aesthetics. Because ‘Sigma.js’ is a ‘javascript’ library, the visualizations are inherently interactive and are well suited for integration with ‘Shiny’ apps. While there are several ‘htmlwidgets’ focused on network visualization, they tend to underperform on medium to large sized graphs. ‘Sigma.js’ was designed for larger network visualizations and this package aims to make those strengths available to ‘R’ users. / MIT	noarch
r-sigmoid	0.3.0	Several different sigmoid functions are implemented, including a wrapper function, SoftMax preprocessing and inverse functions. / GPL-3	noarch
r-signal	0.7_6	A set of signal processing functions originally written for ‘Matlab’ and ‘Octave’. Includes filter generation utilities, filtering functions, resampling routines, and visualization of filter models. It also includes interpolation functions. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-signifreg	2.1	Provide consistent significance controlled variable selection procedure with different directions (forward, backward, stepwise) based on diverse criteria (AIC, BIC, adjusted r-square, and p-value). The algorithm selects a final model with only significant variables based on a correction choice of False Discovery Rate, Bonferroni, or no correction. / GPL-2	noarch
r-signmedian.test	1.5.1	Perform sign test on one-sample data, which is one of the oldest non-parametric statistical methods. Assume that X comes from a continuous distribution with median = v (unknown). Test the null hypothesis H_0 : median of X $v = \mu$ (μ is the location parameter and is given in the test) v.s. the alternative hypothesis H_1 : $v > \mu$ (or $v < \mu$ or $v \neq \mu$) and calculate the p-value. When the sample size is large, perform the asymptotic sign test. In both ways, calculate the R-estimate of location of X and the distribution free confidence interval for μ . / GPL-2	noarch
r-sigopt	0.0.1	Interfaces with the ‘SigOpt’ API. More info at < https://sigopt.com >. / MIT	noarch
r-sigora	3.0.5	Pathway Analysis is the process of statistically linking observations on the molecular level to biological processes or pathways on the systems(i.e. organism, organ, tissue, cell) level. Traditionally, pathway analysis methods regard pathways as collections of single genes and treat all genes in a pathway as equally informative. This can lead to identification of spurious pathways as statistically significant, since components are often shared amongst pathways. SIGORA seeks to avoid this pitfall by focusing on genes or gene-pairs that are (as a combination) specific to a single pathway. In relying on such pathway gene-pair signatures (Pathway-GPS), SIGORA inherently uses the status of other genes in the experimental context to identify the most relevant pathways. The current version allows for pathway analysis of human and mouse datasets and contains pre-computed Pathway-GPS data for pathways in the KEGG and Reactome pathway repositories as well as mechanisms for extracting GPS for user supplied repositories. / GPL-2	noarch
r-sii	1.0.3	This package calculates ANSI S3.5-1997 Speech Intelligibility Index (SII), a standard method for computing the intelligibility of speech from acoustical measurements of speech, noise, and hearing thresholds. This package includes data frames corresponding to Tables 1 - 4 in the ANSI standard as well as a function utilizing these tables and user-provided hearing threshold and noise level measurements to compute the SII score. The methods implemented here extend the standard computations to allow calculation of SII when the measured frequencies do not match those required by the standard by applying interpolation to obtain values for the required frequencies – Development of this package was funded by the Center for Bioscience Education and Technology (CBET) of the Rochester Institute of Technology (RIT). / GPL-2	noarch
r-sim.diffproc	4.4	It provides users with a wide range of tools to simulate, estimate, analyze, and visualize the dynamics of stochastic differential systems in both forms Ito and Stratonovich. Statistical analysis with parallel Monte Carlo and moment equations methods of SDE’s. Enabled many searchers in different domains to use these equations to modeling practical problems in financial and actuarial modeling and other areas of application, e.g., modeling and simulate of first passage time problem in shallow water using the attractive center (Boukhetala K, 1996) ISBN:1-56252-342-2. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-simboot	0.2.6	Provides estimation of simultaneous bootstrap and asymptotic confidence intervals for diversity indices, namely the Shannon and the Simpson index. Several pre-specified multiple comparison types are available to choose. Further user-defined contrast matrices are applicable. In addition, simboot estimates adjusted as well as unadjusted p-values for two of the three proposed bootstrap methods. Further simboot allows for comparing biological diversities of two or more groups while simultaneously testing a user-defined selection of Hill numbers of orders q, which are considered as appropriate and useful indices for measuring diversity. / GPL-2	noarch
r-simcausal	0.5.5	A flexible tool for simulating complex longitudinal data using structural equations, with emphasis on problems in causal inference. Specify interventions and simulate from intervened data generating distributions. Define and evaluate treatment-specific means, the average treatment effects and coefficients from working marginal structural models. User interface designed to facilitate the conduct of transparent and reproducible simulation studies, and allows concise expression of complex functional dependencies for a large number of time-varying nodes. See the package vignette for more information, documentation and examples. / GPL-2	noarch
r-simcdm	0.1.1	Provides efficient R and 'C' routines to simulate cognitive diagnostic model data for Deterministic Input, Noisy And Gate ('DINA') and reduced Reparameterized Unified Model ('rRUM') from Culpepper and Hudson (2017) <doi: 10.1177/0146621617707511>, Culpepper (2015) <doi:10.3102/1076998615595403>, and de la Torre (2009) <doi:10.3102/1076998607309474>. / GPL-2	linux-64, osx-64, win-64
r-simcop	0.7.0	Provides a framework to generating random variates from arbitrary multivariate copulae, while concentrating on (bivariate) extreme value copulae. Particularly useful if the multivariate copulae are not available in closed form. / GPL-2	noarch
r-simctest	2.5	Algorithms for the implementation and evaluation of Monte Carlo tests, as well as for their use in multiple testing procedures. / GPL-2	linux-64, osx-64, win-64
r-simdistr	1.0.1	Assessment of the distributions of baseline continuous and categorical variables in randomised trials. This method is based on the Carlisle-Stouffer method with Monte Carlo simulations. It calculates p-values for each trial baseline variable, as well as combined p-values for each trial - these p-values measure how compatible are distributions of trials baseline variables with random sampling. This package also allows for graphically plotting the cumulative frequencies of computed p-values. Please note that code was partly adapted from Carlisle JB, Loadman JA. (2017) <doi:10.1111/anae.13650>. / GPL-2	noarch
r-simecol	0.8.1	An object oriented framework to simulate ecological (and other) dynamic systems. It can be used for differential equations, individual-based (or agent-based) and other models as well. It supports structuring of simulation scenarios (to avoid copy and paste) and aims to improve readability and re-usability of code. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-simex	1.8	Implementation of the SIMEX-Algorithm by Cook & Stefanski (1994) <doi:10.1080/01621459.1994.10476871> and MCSIMEX by Küchenhoff, Mwalili & Lesaffre (2006) <doi:10.1111/j.1541-0420.2005.00396.x>. / GPL-3	noarch
r-simexaft	1.0.7	Implement of the Simulation-Extrapolation (SIMEX) algorithm for the accelerated failure time (AFT) with covariates subject to measurement error. / GPL-3	noarch
r-simframe	0.5.3	A general framework for statistical simulation. / GPL-2	linux-64, osx-64, win-64
r-simhaz	0.1	Generate power for the Cox proportional hazards model by simulating survival events data with time dependent exposure status for subjects. A dichotomous exposure variable is considered with a single transition from unexposed to exposed status during the subject's time on study. / GPL-2	noarch
r-similar	1.0.6	An implementation of a novel method to quantify the similarity the code-base of R functions by means of program dependence graphs. Possible use cases include detection of code clones for improving software quality and of plagiarism among students' homework assignments. / GPL-3	linux-64, osx-64, win-64
r-similaritymeasures	1.4	Functions to run and assist four different similarity measures. The similarity measures included are: longest common subsequence (LCSS), Frechet distance, edit distance and dynamic time warping (DTW). Each of these similarity measures can be calculated from two n-dimensional trajectories, both in matrix form. / GPL-3	noarch
r-simile	1.3.3	Allows a Simile model saved as a compiled binary to be loaded, parameterized, executed and interrogated. This version works with Simile v5.97 on. / Unlimited	noarch
r-siminf	6.3.0	Provides an efficient and very flexible framework to conduct data-driven epidemiological modeling in realistic large scale disease spread simulations. The framework integrates infection dynamics in subpopulations as continuous-time Markov chains using the Gillespie stochastic simulation algorithm and incorporates available data such as births, deaths and movements as scheduled events at predefined time-points. Using C code for the numerical solvers and 'OpenMP' (if available) to divide work over multiple processors ensures high performance when simulating a sample outcome. One of our design goals was to make the package extendable and enable usage of the numerical solvers from other R extension packages in order to facilitate complex epidemiological research. The package contains template models and can be extended with user-defined models. / GPL-3	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-simmer	4.3.0	A process-oriented and trajectory-based Discrete-Event Simulation (DES) package for R. It is designed as a generic yet powerful framework. The architecture encloses a robust and fast simulation core written in ‘C’ with automatic monitoring capabilities. It provides a rich and flexible R API that revolves around the concept of trajectory, a common path in the simulation model for entities of the same type. Documentation about ‘simmer’ is provided by several vignettes included in this package, via the paper by Ucar, Smeets & Azcorra (2019, <doi:10.18637/jss.v090.i02>), and the paper by Ucar, Hernández, Serrano & Azcorra (2018, <doi:10.1109/MCOM.2018.1700960>); see ‘citation(simmer)’ for details. / GPL-2	linux-64, osx-64, win-64
r-simml	0.1.0	A major challenge in estimating treatment decision rules from a randomized clinical trial dataset with covariates measured at baseline lies in detecting relatively small treatment effect modification-related variability (i.e., the treatment-by-covariates interaction effects on treatment outcomes) against a relatively large non-treatment-related variability (i.e., the main effects of covariates on treatment outcomes). The class of Single-Index Models with Multiple-Links is a novel single-index model specifically designed to estimate a single-index (a linear combination) of the covariates associated with the treatment effect modification-related variability, while allowing a nonlinear association with the treatment outcomes via flexible link functions. The models provide a flexible regression approach to developing treatment decision rules based on patients’ data measured at baseline. We refer to Petkova, Tarpey, Su, and Ogden (2017) <doi: 10.1093/biostatistics/kxw035> and A constrained single-index model for estimating interactions between a treatment and covariates (under review, 2019) for detail. The main function of this package is simml(). / GPL-3	noarch
r-simms	1.2.0	Algorithms to create prognostic biomarkers using biological genesets or networks. / GPL-2	noarch
r-simone	1.0.4	Implements the inference of co-expression networks based on partial correlation coefficients from either steady-state or time-course transcriptomic data. Note that with both type of data this package can deal with samples collected in different experimental conditions and therefore not identically distributed. In this particular case, multiple but related networks are inferred on one simone run. / GPL-2	linux-64, osx-64, win-64
r-simphe	0.2.0	Provides functions to simulate single or multiple, independent or correlated phenotype(s) with additive, dominance effects and their interactions. Also includes functions to generate phenotype(s) with specific heritability. Flexible and user-friendly options for simulation. / GPL-2	noarch
r-simpleboot	1.1.7	Simple bootstrap routines. / GPL-2	noarch
r-simplecache	0.4.1	Provides intuitive functions for caching R objects, encouraging reproducible, restartable, and distributed R analysis. The user selects a location to store caches, and then provides nothing more than a cache name and instructions (R code) for how to produce the R object. Also provides some advanced options like environment assignments, recreating or reloading caches, and cluster compute bindings (using the ‘batchtools’ package) making it flexible enough for use in large-scale data analysis projects. / BSD_2_clause	noarch
r-simplegraph	1.0.0	Simple classic graph algorithms for simple graph classes. Graphs may possess vertex and edge attributes. ‘simplegraph’ has no dependencies and it is written entirely in R, so it is easy to install. / MIT	noarch
r-simpleneural	0.1.1	Trains neural networks (multilayer perceptrons with one hidden layer) for bi- or multi-class classification. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-simplercache	0.3.2	Simple result caching in R based on R.cache. The global environment is not considered when caching results simplifying moving files between multiple instances of R. Relies on more base functions than R.cache (e.g. cached results are saved using saveRDS() and readRDS()). / LGPL-3	noarch
r-simplesetup	0.1.0	When working across multiple machines and, similarly for reproducible research, it can be time consuming to ensure that you have all of the needed packages installed and loaded and that the correct working directory is set. 'simpleSetup' provides simple functions for making these tasks more straightforward. / GPL-3	noarch
r-simplicialcubature	1.2	Provides methods to integrate functions over m-dimensional simplices in n-dimensional Euclidean space. There are exact methods for polynomials and adaptive methods for integrating an arbitrary function. Dirichlet probabilities are calculated in certain cases. / GPL-2	noarch
r-simputation	0.2.3	Easy to use interfaces to a number of imputation methods that fit in the not-a-pipe operator of the 'magrittr' package. / GPL-3	linux-64, osx-64, win-64
r-simsalapar	1.0_1	Tools for setting up (design), conducting, and evaluating large-scale simulation studies with graphics and tables, including parallel computations. / GPL-2 GPL-3	noarch
r-simscrpiecwise	0.1.1	Contains two functions for simulating survival data from piecewise exponential hazards with a proportional hazards adjustment for covariates. The first function SimUNIVPiecewise simulates univariate survival data based on a piecewise exponential hazard, covariate matrix and true regression vector. The second function SimSCRPIecwise semi-competing risks data based on three piecewise exponential hazards, three true regression vectors and three matrices of patient covariates (which can be different or the same). This simulates from the Semi-Markov model of Lee et al (2015) given patient covariates, regression parameters, patient frailties and baseline hazard functions. / GPL-2	noarch
r-simsem	0.5_1	Provides an easy framework for Monte Carlo simulation in structural equation modeling, which can be used for various purposes, such as such as model fit evaluation, power analysis, or missing data handling and planning. / GPL-2	noarch
r-simsv	0.2.3	Simulate survival times from standard parametric survival distributions (exponential, Weibull, Gompertz), 2-component mixture distributions, or a user-defined hazard, log hazard, cumulative hazard, or log cumulative hazard function. Baseline covariates can be included under a proportional hazards assumption. Time dependent effects (i.e. non-proportional hazards) can be included by interacting covariates with linear time or a user-defined function of time. Clustered event times are also accommodated. The 2-component mixture distributions can allow for a variety of flexible baseline hazard functions reflecting those seen in practice. If the user wishes to provide a user-defined hazard or log hazard function then this is possible, and the resulting cumulative hazard function does not need to have a closed-form solution. Note that this package is modelled on the 'survsim' package available in the 'Stata' software (see Crowther and Lambert (2012) < http://www.stata-journal.com/sjpdf.html?articlenum=st0275 > or Crowther and Lambert (2013) <doi:10.1002/sim.5823>). / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-simtimer	4.0.0	Handles datetimes as integers for the usage inside Discrete-Event Simulations (DES). The conversion is made using the internally generic function <code>as.numeric()</code> of the base package. DES is described in Simulation Modeling and Analysis by Averill Law and David Kelton (1999) <doi:10.2307/2288169>. / GPL-3	noarch
r-simulator	0.2.0	A framework for performing simulations such as those common in methodological statistics papers. The design principles of this package are described in greater depth in Bien, J. (2016) The simulator: An Engine to Streamline Simulations, which is available at < http://faculty.bscb.cornell.edu/~bien/simulator.pdf >. / GPL-3	noarch
r-simule	1.3.0	This is an R implementation of a constrained l1 minimization approach for estimating multiple Sparse Gaussian or Nonparanormal Graphical Models (SIMULE). The SIMULE algorithm can be used to estimate multiple related precision matrices. For instance, it can identify context-specific gene networks from multi-context gene expression datasets. By performing data-driven network inference from high-dimensional and heterogenous data sets, this tool can help users effectively translate aggregated data into knowledge that take the form of graphs among entities. Please run <code>demo(simuleDemo)</code> to learn the basic functions provided by this package. For further details, please read the original paper: Beilun Wang, Ritambhara Singh, Yanjun Qi (2017) <DOI:10.1007/s10994-017-5635-7>. / GPL-2	noarch
r-sin	0.6	This package provides routines to perform SIN model selection as described in Drton & Perlman (2004, 2008). The selected models are represented in the format of the ‘ggm’ package, which allows in particular parameter estimation in the selected model. / GPL-2	noarch
r-sinaplot	1.1.0	The sinaplot is a data visualization chart suitable for plotting any single variable in a multiclass data set. It is an enhanced jitter strip chart, where the width of the jitter is controlled by the density distribution of the data within each class. / GPL-2	noarch
r-sinib	1.0.0	Density, distribution function, quantile function and random generation for the sum of independent non-identical binomial distribution with parameters <code>code{size}</code> and <code>code{prob}</code> . / GPL-3	noarch
r-sirad	2.3_3	Calculating daily global solar radiation at horizontal surface using several well-known models (i.e. Angstrom-Prescott, Supit-Van Kappel, Hargreaves, Bristow and Campbell, and Mahmood-Hubbard), and model calibration based on ground-truth data, and (3) model auto-calibration. The FAO Penmann-Monteith equation to calculate evapotranspiration is also included. / GPL-2	noarch
r-sisvive	1.4	Selects invalid instruments amongst a candidate of potentially bad instruments. The algorithm selects potentially invalid instruments and provides an estimate of the causal effect between exposure and outcome. / GPL-2	noarch
r-sitmo	2.0.1	Provided within are two high quality and fast PPRNGs that may be used in an ‘OpenMP’ parallel environment. In addition, there is a generator for one dimensional low-discrepancy sequence. The objective of this library to consolidate the distribution of the ‘sitmo’ (C98 & C11), ‘threefry’ and ‘vandercompt’ (C11-only) engines on CRAN by enabling others to link to the header files inside of ‘sitmo’ instead of including a copy of each engine within their individual package. Lastly, the package contains example implementations using the ‘sitmo’ package and three accompanying vignette that provide additional information. / MIT	linux-64, osx-64, win-64
r-sitools	1.4	Format a number (or a list of numbers) to a string (or a list of strings) with SI prefix. Use SI prefixes as constants like $(4 * \text{milli})^2$ / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sitree	0.1_7	Forecasts plots at tree level. / GPL-2	noarch
r-sizer	0.1_5	Calculates and plots the SiZer map for scatterplot data. A SiZer map is a way of examining when the p-th derivative of a scatterplot-smoother is significantly negative, possibly zero or significantly positive across a range of smoothing bandwidths. / GPL-2	noarch
r-sjdbc	1.6.0	Provides a database-independent JDBC interface. / BSD_3_clause	noarch
r-skat	1.3.2	Functions for kernel-regression-based association tests including Burden test, SKAT and SKAT-O. These methods aggregate individual SNP score statistics in a SNP set and efficiently compute SNP-set level p-values. / GPL-2	linux-64, osx-64, win-64
r-skda	0.1	Sparse (Multicategory) Kernel Discriminant Analysis does variable selection for nonparametric classification / GPL-2	linux-64, osx-64, win-64
r-skeletor	1.0.4	A tool for bootstrapping new packages with useful defaults, including a test suite outline that passes checks and helpers for running tests, checking test coverage, building vignettes, and more. Package skeletons it creates are set up for pushing your package to 'GitHub' and using other hosted services for building and test automation. / MIT	noarch
r-skellam	0.2.0	Functions for the Skellam distribution, including: density (pmf), cdf, quantiles and regression. / GPL-2	noarch
r-skewt	0.1	Density, distribution function, quantile function and random generation for the skewed t distribution of Fernandez and Steel. / GPL-3	noarch
r-skmeans	0.2_1	Algorithms to compute spherical k-means partitions. Features several methods, including a genetic and a fixed-point algorithm and an interface to the CLUTO vcluster program. / GPL-2	noarch
r-skywatchr	0.8_2	Query and download satellite imagery and climate/atmospheric datasets using the SkyWatch API. Search datasets by wavelength (band), cloud cover, resolution, location, date, etc. Get the query results as data frame and as HTML. To learn more about the SkyWatch API, see < https://github.com/skywatchspaceapps/api >. / GPL-2	noarch
r-slam	0.1_4	Data structures and algorithms for sparse arrays and matrices, based on index arrays and simple triplet representations, respectively. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-slc	0.3	Estimates the slope and level change present in data after removing phase A trend. Represents graphically the original and the detrended data. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sldassay	1.8	Calculates maximum likelihood estimate, exact and asymptotic confidence intervals, and exact and asymptotic goodness of fit p-values for concentration of infectious units from serial limiting dilution assays. This package uses the likelihood equation, exact goodness of fit p-values, and exact confidence intervals described in Meyers et al. (1994) < http://jcm.asm.org/content/32/3/732.full.pdf >. This software is also implemented as a web application through the Shiny R package < https://iupm.shinyapps.io/sldassay/ >. / GPL-3	noarch
r-sleekts	1.0.2	Compute Time series Resistant Smooth 4253H, twice smoothing method. / GPL-3	noarch
r-sleepr	0.3.0	Use behavioural variables to score activity and infer sleep from bouts of immobility. It is primarily designed to score sleep in fruit flies from Drosophila Activity Monitor (TriKinetics) and Ethoscope data. It implements sleep scoring using the five-minute rule (Hendricks et al. (2000) <DOI:10.1016/S0896-6273(00)80877-6>), activity classification for Ethoscopes (Geissmann et al. (2017) <DOI:10.1371/journal.pbio.2003026>) and a new algorithm to detect when animals are dead. / GPL-3	noarch
r-sleuth2	2.0_5	Data sets from Ramsey, F.L. and Schafer, D.W. (2002), The Statistical Sleuth: A Course in Methods of Data Analysis (2nd ed), Duxbury. / GPL-2	noarch
r-sleuth3	1.0_3	Data sets from Ramsey, F.L. and Schafer, D.W. (2013), The Statistical Sleuth: A Course in Methods of Data Analysis (3rd ed), Cengage Learning. / GPL-2	noarch
r-slfm	1.0.0	Set of tools to find coherent patterns in microarray data using a Bayesian Sparse Latent Factor Model - SLFM; see Duarte and Mayrink (2015) <DOI:10.1007/978-3-319-12454-4_15>. Considerable effort has been put into making slfm fast and memory efficient, turning it an interesting alternative to simpler methods in terms of execution time. It implements versions of the SLFM based on two type of mixtures priors for the loadings: one relying on a degenerate component at zero and the other using a small variance normal distribution for the spike part of the mixture. It also implements additional functions to allow pre-processing procedures for the data and to fit the model for a large number of probesets or genes. / GPL-2	linux-64, osx-64, win-64
r-slhd	2.1_1	Generate the optimal Latin Hypercube Designs (LHDs) for computer experiments with quantitative factors and the optimal Sliced Latin Hypercube Designs (SLHDs) for computer experiments with both quantitative and qualitative factors. Details of the algorithm can be found in Ba, S., Brennenman, W. A. and Myers, W. R. (2015), Optimal Sliced Latin Hypercube Designs, Technometrics. Important function in this package is maximinSLHD. / LGPL-2.1	linux-64, osx-64, win-64
r-slickr	0.2.4	Create and customize interactive carousels using the ‘Slick’ JavaScript library and the ‘htmlwidgets’ package. The carousels can contain plots produced in R, images, ‘iframes’, videos and other ‘htmlwidgets’. These carousels can be used directly from the R console, from ‘RStudio’, in Shiny apps and R Markdown documents. / MIT	noarch
r-slide	1.0.0	This statistical method uses the nearest neighbor algorithm to estimate absolute distances between single cells based on a chosen constellation of surface proteins, with these distances being a measure of the similarity between the two cells being compared. Based on Sen, N., Mukherjee, G., and Arvin, A.M. (2015) <DOI:10.1016/j.ymeth.2015.07.008>. / GPL-3	noarch
r-slideview	0.1.0	Create a side-by-side view of raster(image)s with an interactive slider to switch between regions of the images. This can be especially useful for image comparison of the same region at different time stamps. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-slim	0.1.1	Fits singular linear models to longitudinal data. Singular linear models are useful when the number, or timing, of longitudinal observations may be informative about the observations themselves. They are described in Farewell (2010) <doi:10.1093/biomet/asp068>, and are extensions of the linear increments model <doi:10.1111/j.1467-9876.2007.00590.x> to general longitudinal data. / GPL-3	noarch
r-slippymath	0.3.1	Provides functions for performing common tasks when working with slippy map tile service APIs e.g. Google maps, Open Street Map, Mapbox, Stamen, among others. Functionality includes converting from latitude and longitude to tile numbers, determining tile bounding boxes, and compositing tiles to a georeferenced raster image. / MIT	noarch
r-slope	0.1.3	Efficient procedures for Sorted L1 Penalized Estimation (SLOPE). The sorted L1 norm is useful for statistical estimation and testing, particularly for variable selection in the linear model. / GPL-3	linux-64, osx-64, win-64
r-slouch	2.1.2	An implementation of a phylogenetic comparative method. It can fit univariate among-species Ornstein-Uhlenbeck models of phenotypic trait evolution, where the trait evolves towards a primary optimum. The optimum can be modelled as a single parameter, as multiple discrete regimes on the phylogenetic tree, and/or with continuous covariates. See also Hansen (1997) doi:10.2307/2411186, Butler & King (2004) doi:10.1086/426002, Hansen et al. (2008) doi:10.1111/j.1558-5646.2008.00412.x. / GPL-2	noarch
r-slp	1.0_5	Interface for creation of ‘slp’ class smoother objects for use in Generalized Additive Models (as implemented by packages ‘gam’ and ‘mgcv’). / GPL-2	linux-64, osx-64, win-64
r-sm	2.2_5	This is software linked to the book ‘Applied Smoothing Techniques for Data Analysis - The Kernel Approach with S-Plus Illustrations’ Oxford University Press. / GPL-2	linux-64, osx-64, win-64
r-smaa	0.3_0	Implementation of the Stochastic Multi-Criteria Acceptability Analysis (SMAA) family of Multiple Criteria Decision Analysis (MCDA) methods. / GPL-3	linux-64, osx-64, win-64
r-smac	1.0	This package provides a solution path for L1-penalized angle-based classification. Three loss functions are implemented in smac, including the deviance loss in logistic regression, the exponential loss in boosting, and the proximal support vector machine loss. / GPL-2	linux-64, osx-64, win-64
r-smallarea	0.1	Inference techniques for Fay Herriot Model. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-smartsizer	1.0.1	A set of tools for determining the necessary sample size in order to identify the optimal dynamic treatment regime in a sequential, multiple assignment, randomized trial (SMART). Utilizes multiple comparisons with the best methodology to adjust for multiple comparisons. Designed for an arbitrary SMART design. Please see Artman (2018) <arXiv:1804.04587> for more details. / GPL-3	noarch
r-smatr	3.4_8	Methods for fitting bivariate lines in allometry using the major axis (MA) or standardised major axis (SMA), and for making inferences about such lines. The available methods of inference include confidence intervals and one-sample tests for slope and elevation, testing for a common slope or elevation amongst several allometric lines, constructing a confidence interval for a common slope or elevation, and testing for no shift along a common axis, amongst several samples. See Warton et al. 2012 <doi:10.1111/j.2041-210X.2011.00153.x> for methods description. / GPL-2	noarch
r-smc	1.1	particle filtering, auxiliary particle filtering and sequential Monte Carlo algorithms / GPL-2	linux-64, osx-64, win-64
r-smcfcs	1.4.0	Implements multiple imputation of missing covariates by Substantive Model Compatible Fully Conditional Specification. This is a modification of the popular FCS/chained equations multiple imputation approach, and allows imputation of missing covariate values from models which are compatible with the user specified substantive model. / GPL-3	noarch
r-smco	0.1	This package is for optimizing non-linear complex functions based on Monte Carlo random sampling. / GPL-2	noarch
r-smcrm	0.0_3	Data Sets for Kumar and Petersen (2012). Statistical Methods in Customer Relationship Management, Wiley: New York. / GPL-3	noarch
r-smcure	2.0	An R-package for Estimating Semiparametric PH and AFT Mixture Cure Models / GPL-2	noarch
r-smdata	1.2	Contains data files to accompany Smithson & Merkle (2013), Generalized Linear Models for Categorical and Continuous Limited Dependent Variables. / GPL-2	noarch
r-smds	1.0	Symbolic multidimensional scaling for interval-valued dissimilarities. The hypersphere model and the hyperbox model are available. / GPL-2	linux-64, osx-64, win-64
r-sme	1.0.2	Fit smoothing-splines mixed-effects models to replicated functional data sets and visualise the results. / GPL-3	linux-64, osx-64, win-64
r-smfilter	1.0.3	Provides the filtering algorithms for the state space models on the Stiefel manifold as well as the corresponding sampling algorithms for uniform, vector Langevin-Bingham and matrix Langevin-Bingham distributions on the Stiefel manifold. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-smfsb	1.3	Code and data for modelling and simulation of stochastic kinetic biochemical network models. It contains the code and data associated with the second and third editions of the book Stochastic Modelling for Systems Biology, published by Chapman & Hall/CRC Press. / LGPL-3	linux-64, osx-64, win-64
r-smirnov	1.0.1	This tiny package contains one function <code>smirnov()</code> which calculates two scaled taxonomic coefficients, <code>Txy</code> (coefficient of similarity) and <code>Txx</code> (coefficient of originality). These two characteristics may be used for the analysis of similarities between any number of taxonomic groups, and also for assessing uniqueness of giving taxon. It is possible to use <code>smirnov()</code> output as a distance measure: convert it to distance by <code>as.dist(1 - smirnov(x))</code> . / GPL-2	noarch
r-smisc	0.3.9	A collection of functions for statistical computing and data manipulation in R. Includes routines for data ingestion, operating on dataframes and matrices, conversion to and from lists, converting factors, filename manipulation, programming utilities, parallelization, plotting, statistical and mathematical operations, and time series. / BSD_3_clause	linux-64, osx-64, win-64
r-smithwilsonyieldcurve	1.0.1	Constructs a yield curve by the Smith-Wilson method from a table of LIBOR and SWAP rates / GPL-3	noarch
r-smitidvisu	0.0.6	Visualisation tools for 'SMITIDstruct' package. Allow to visualize host timeline, transmission tree, index diversities and variant graph using HTMLwidgets. It mainly using D3JS javascript framework. / GPL-3	linux-64, osx-64, win-64
r-smloutliers	0.1	Local Correlation Integral (LOCI) method for outlier identification is implemented here. The LOCI method developed here is invented in Breunig, et al. (2000), see <doi:10.1145/342009.335388>. / GPL-2	noarch
r-smma	1.0.2	Efficient design matrix free procedure for solving a soft maximin problem for large scale array-tensor structured models. Currently Lasso and SCAD penalized estimation is implemented. / GPL-2	linux-64, osx-64, win-64
r-smoother	1.1	A collection of methods for smoothing numerical data, commencing with a port of the Matlab gaussian window smoothing function. In addition, several functions typically used in smoothing of financial data are included. / GPL-2	noarch
r-smoothhazard	1.4.1	Estimation of two-state (survival) models and irreversible illness-death models with possibly interval-censored, left-truncated and right-censored data. Proportional intensities regression models can be specified to allow for covariates effects separately for each transition. We use either a parametric approach with Weibull baseline intensities or a semi-parametric approach with M-splines approximation of baseline intensities in order to obtain smooth estimates of the hazard functions. Parameter estimates are obtained by maximum likelihood in the parametric approach and by penalized maximum likelihood in the semi-parametric approach. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-smoothhr	1.0.2	Provides flexible hazard ratio curves allowing non-linear relationships between continuous predictors and survival. To better understand the effects that each continuous covariate has on the outcome, results are expressed in terms of hazard ratio curves, taking a specific covariate value as reference. Confidence bands for these curves are also derived. / GPL-2	noarch
r-smoothie	1.0.1	Functions to smooth two-dimensional fields using FFT and the convolution theorem / GPL-2	noarch
r-smoothmest	0.1.2	Some M-estimators for 1-dimensional location (Bisquare, ML for the Cauchy distribution, and the estimators from application of the smoothing principle introduced in Hampel, Hennig and Ronchetti (2011) to the above, the Huber M-estimator, and the median, main function is smoothm), and Pitman estimator. / GPL-3	noarch
r-smoothsurv	2.0.1	Contains, as a main contribution, a function to fit a regression model with possibly right, left or interval censored observations and with the error distribution expressed as a mixture of G-splines. Core part of the computation is done in compiled C written using the Scythe Statistical Library Version 0.3. / GPL-2	linux-64, osx-64, win-64
r-smpracticals	1.4.3	Contains the datasets and a few functions for use with the practicals outlined in Appendix A of the book Statistical Models (Davison, 2003, Cambridge University Press). The practicals themselves can be found at http://statwww.epfl.ch/davison/SM/ . / GPL-2	noarch
r-smr	2.0.1	Computes the studentized midrange distribution (pdf, cdf and quantile) and generates random numbers / GPL-2	noarch
r-sms	2.3.1	Produce small area population estimates by fitting census data to survey data. / GPL-3	noarch
r-smss	1.0.2	Datasets used in Statistical Methods for the Social Sciences (SMSS) by Alan Agresti and Barbara Finlay. / GPL-3	noarch
r-smvar	1.3.3	Implements the structural model for variances in order to detect differentially expressed genes from gene expression data / GPL-3	noarch
r-sn	1.5.4	Build and manipulate probability distributions of the skew-normal family and some related ones, notably the skew-t family, and provide related statistical methods for data fitting and model diagnostics, in the univariate and the multivariate case. / GPL-2 GPL-3	noarch
r-snakecase	0.11.0	A consistent, flexible and easy to use tool to parse and convert strings into cases like snake or camel among others. / GPL-3	noarch
r-snakecharm	1.0.7	Run 'Python' code, make function calls, assign and retrieve variables, etc. from R. A fork from 'rPython' which uses 'jsonlite', 'Rcpp' and has several fixes and improvements. / GPL-2	linux-64, osx-64
r-snakesandladdersanalysis	2.1.0	Plays the game of Snakes and Ladders and has tools for analyses. The tools included allow you to find the average moves to win, frequency of each square, importance of the snakes and the ladders, the most common square and the plotting of the game played. / GPL-2	noarch
r-snappier	0.1.0	Compression and decompression with 'Snappy'. / BSD_3_clause	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-snapshot	0.1.2	Functions for reading and writing Gadget N-body snapshots. The Gadget code is popular in astronomy for running N-body / hydrodynamical cosmological and merger simulations. To find out more about Gadget see the main distribution page at www.mpa-garching.mpg.de/gadget/ / GPL-2	noarch
r-snem	0.1.0	Efficient estimation of multivariate skew-normal distribution in closed form. / GPL-2	noarch
r-snipem	1.0.1	Snipping methods optimally removing scattered cells for robust estimation and cluster analysis. / GPL-2	linux-64, osx-64, win-64
r-snn	1.1	Implement K-nearest neighbor classifier, weighted nearest neighbor classifier, bagged nearest neighbor classifier, optimal weighted nearest neighbor classifier and stabilized nearest neighbor classifier, and perform model selection via 5 fold cross-validation for them. This package also provides functions for computing the classification error and classification instability of a classification procedure. / GPL-3	noarch
r-snnr	1.0	Solve the problem of over-parameterization in neural networks for genomic selection. Daniel Gianola, Hayrettin OkutEmail, Kent A Weigel and Guilherme JM Rosa (2011) < doi:10.1186/1471-2156-12-87 >. / GPL-2	linux-64, osx-64, win-64
r-snow	0.4.3	Support for simple parallel computing in R. / GPL-3	noarch
r-snowballc	0.6.0	An R interface to the C libstemmer library that implements Porter's word stemming algorithm for collapsing words to a common root to aid comparison of vocabulary. Currently supported languages are Danish, Dutch, English, Finnish, French, German, Hungarian, Italian, Norwegian, Portuguese, Romanian, Russian, Spanish, Swedish and Turkish. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-snowflakes	1.0.0	The function generates and plots random snowflakes. Each snowflake is defined by a given diameter, width of the crystal, color, and random seed. Snowflakes are plotted in such way that they always remain round, no matter what the aspect ratio of the plot is. Snowflakes can be created using transparent colors, which creates a more interesting, somewhat realistic, image. Images of the snowflakes can be separately saved as svg files and used in websites as static or animated images. / GPL-2	noarch
r-snpar	1.0	contains several supplementary non-parametric statistics methods including quantile test, Cox-Stuart trend test, runs test, normal score test, kernel PDF and CDF estimation, kernel regression estimation and kernel Kolmogorov-Smirnov test. / GPL-2	noarch
r-snpmaxsel	1.0.3	This package implements asymptotic methods related to maximally selected statistics, with applications to SNP data. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sns	1.1.2	Stochastic Newton Sampler (SNS) is a Metropolis-Hastings-based, Markov Chain Monte Carlo sampler for twice differentiable, log-concave probability density functions (PDFs) where the proposal density function is a multivariate Gaussian resulting from a second-order Taylor-series expansion of log-density around the current point. The mean of the Gaussian proposal is the full Newton-Raphson step from the current point. A Boolean flag allows for switching from SNS to Newton-Raphson optimization (by choosing the mean of proposal function as next point). This can be used during burn-in to get close to the mode of the PDF (which is unique due to concavity). For high-dimensional densities, mixing can be improved via ‘state space partitioning’ strategy, in which SNS is applied to disjoint subsets of state space, wrapped in a Gibbs cycle. Numerical differentiation is available when analytical expressions for gradient and Hessian are not available. Facilities for validation and numerical differentiation of log-density are provided. / GPL-2	noarch
r-soar	0.99	Allows objects to be stored on disc and automatically recalled into memory, as required, by delayed assignment. / GPL-2 GPL-3	noarch
r-sobolsequence	1.0	R implementation of S. Joe and F. Y. Kuo(2008) <DOI:10.1137/070709359>. The implementation is based on the data file new-joe-kuo-6.21201 < http://web.maths.unsw.edu.au/~fkuo/sobol/ >. / BSD_3_clause	linux-64, osx-64, win-64
r-soccer	0.1.1	Functions for evaluating tournament predictions, simulating results from individual soccer matches and tournaments. See < http://sandsynligvis.dk/2018/08/03/world-cup-prediction-winners/ > for more information. / GPL-2	linux-64, osx-64, win-64
r-social	1.0	A set of functions to quantify and visualise social autocorrelation. / GPL-2	linux-64, osx-64, win-64
r-socialnetworks	1.1	Generates social networks using either of two approaches: using either pairwise distances or territorial area intersections. / GPL-3	linux-64, osx-64, win-64
r-socialposition	1.0.1	Provides to sociologists (and related scientists) a toolbox to facilitate the construction of social position indicators from survey data. Social position indicators refer to what is commonly known as social class and social status. There exists in the sociological literature many theoretical conceptualisation and empirical operationalization of social class and social status. This first version of the package offers tools to construct the International Socio-Economic Index of Occupational Status (ISEI) and the Oesch social class schema. It also provides tools to convert several occupational classifications (PCS82, PCS03, and ISCO08) into a common one (ISCO88) to facilitate data harmonisation work, and tools to collapse (i.e. group) modalities of social position indicators. / GPL-2 GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-soda	1.0_6	Functions, examples and other software related to the book Software for Data Analysis: Programming with R. See package?SoDA for an overview. / GPL-2	linux-64, osx-64, win-64
r-sodavis	1.2	Variable and interaction selection are essential to classification in high-dimensional setting. In this package, we provide the implementation of SODA procedure, which is a forward-backward algorithm that selects both main and interaction effects under logistic regression and quadratic discriminant analysis. We also provide an extension, S-SODA, for dealing with the variable selection problem for semi-parametric models with continuous responses. / GPL-2	noarch
r-sofia	1.0	Software that leverages the capabilities of Circos by manipulating data, preparing configuration files, and running the Perl-native Circos directly from the R environment with minimal user intervention. Circos is a novel software that addresses the challenges in visualizing genetic data by creating circular ideograms composed of tracks of heatmaps, scatter plots, line plots, histograms, links between common markers, glyphs, text, and etc. Please see < http://www.circos.ca >. / GPL-3	noarch
r-softclustering	1.19012	It contains soft clustering algorithms, in particular approaches derived from rough set theory: Lingras & West original rough k-means, Peters' refined rough k-means, and PI rough k-means. It also contains classic k-means and a corresponding illustrative demo. / GPL-2	noarch
r-softimpute	1.4	Iterative methods for matrix completion that use nuclear-norm regularization. There are two main approaches. The one approach uses iterative soft-thresholded svds to impute the missing values. The second approach uses alternating least squares. Both have an EM flavor, in that at each iteration the matrix is completed with the current estimate. For large matrices there is a special sparse-matrix class named Incomplete that efficiently handles all computations. The package includes procedures for centering and scaling rows, columns or both, and for computing low-rank SVDs on large sparse centered matrices (i.e. principal components) / GPL-2	linux-64, osx-64, win-64
r-softmaxreg	1.2	Implementation of 'softmax' regression and classification models with multiple layer neural network. It can be used for many tasks like word embedding based document classification, 'MNIST' dataset handwritten digit recognition and so on. Multiple optimization algorithm including 'SGD', 'Adagrad', 'RM-Sprop', 'Moment', 'NAG', etc are also provided. / GPL-2	noarch
r-softrandomforest	0.1.0	Performs random forests for soft decision trees for a classification problem. Current limitations are for a maximum depth of 5 resulting in 16 terminal nodes. Some data cleaning is required before input. Final graphic output requires currently requires exporting to 'Microsoft Excel' for visualization. Method based on Irsoy, Yildiz and Alpaydin (2012, ISBN: 978-4-9906441-1-6). / CC0	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-soilhyp	0.1.3	Provides functions for (1) soil water retention (SWC) and unsaturated hydraulic conductivity (Ku) (van Genuchten-Mualem (vGM or vG) [1, 2], Peters-Durner-Iden (PDI) [3, 4, 5], Brooks and Corey (bc) [8]), (2) fitting of parameter for SWC and/or Ku using Shuffled Complex Evolution (SCE) optimisation and (3) calculation of soil hydraulic properties (Ku and soil water contents) based on the simplified evaporation method (SEM) [6, 7]. Main references: [1] van Genuchten (1980) <doi:10.2136/sssaj1980.03615995004400050002x>, Mualem (1976) <doi:10.1029/WR012i003p00513>, [3] Peters (2013) <doi:10.1002/wrcr.20548>, Iden and Durner (2013) <doi:10.1002/2014WR015937>, [5] Peters (2014) <doi:10.1002/2014WR015937>, [6] Wind G. P. (1966), [7] Peters and Durner (2008) <doi:10.1016/j.jhydrol.2008.04.016> and [8] Brooks and Corey (1964). / GPL-2	noarch
r-soilphysics	3.1	Basic and model-based soil physical analyses. / GPL-2	noarch
r-soiltexture	1.5.1	The Soil Texture Wizard is a set of R functions designed to produce texture triangles (also called texture plots, texture diagrams, texture ternary plots), classify and transform soil textures data. These functions virtually allows to plot any soil texture triangle (classification) into any triangle geometry (isosceles, right-angled triangles, etc.). This set of function is expected to be useful to people using soil textures data from different soil texture classification or different particle size systems. Many (> 15) texture triangles from all around the world are predefined in the package. A simple text based graphical user interface is provided: soiltexture_gui(). / AGPL-3	noarch
r-soilwater	1.0.5	It implements parametric formulas of soil water retention or conductivity curve. At the moment, only Van Genuchten (for soil water retention curve) and Mualem (for hydraulic conductivity) were implemented. See reference (< http://en.wikipedia.org/wiki/Water_retention_curve >). / GPL-2	noarch
r-sokoban	0.1.0	Interactively play a game of sokoban ,which has nine game levels.Sokoban is a type of transport puzzle, in which the player pushes boxes or crates around in a warehouse, trying to get them to storage locations. / GPL-3	noarch
r-solar	0.44	Calculation methods of solar radiation and performance of photovoltaic systems from daily and intradaily irradiation data sources. / GPL-3	noarch
r-solarpos	1.0	Calculation of solar zenith and azimuth angles. / GPL-2	noarch
r-solartime	0.0.1	Provide utilities to work with solar time, i.e. where noon is exactly when sun culminates. Provides functions for computing sun position and times of sunrise and sunset. / GPL-3	noarch
r-solomon	1.0	Parentage analysis using Bayes' theorem / GPL-2	noarch
r-solrad	1.0.0	For surface energy models and estimation of solar positions and components with varying topography, time and locations. The functions calculate solar top-of-atmosphere, open, diffuse and direct components, atmospheric transmittance and diffuse factors, day length, sunrise and sunset, solar azimuth, zenith, altitude, incidence, and hour angles, earth declination angle, equation of time, and solar constant. Details about the methods and equations are explained in Seyednasrollah, Bijan, Mukesh Kumar, and Timothy E. Link. 'On the role of vegetation density on net snow cover radiation at the forest floor.' Journal of Geophysical Research: Atmospheres 118.15 (2013): 8359-8374, <doi:10.1002/jgrd.50575>. / AGPL-3	noarch
r-solverationalmatrixequation	0.1.0	Given a symmetric positive definite matrix Q and a non-singular matrix L, find symmetric positive definite solution X such that $X = Q L (X \text{ inv}) L^T$. Reference: Benner, P., Faßbender, H. On the Solution of the Rational Matrix Equation. Benner, Faßbender (2007) <doi:10.1155/2007/21850>. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-som	0.3.5	Self-Organizing Map (with application in gene clustering). / GPL-3	linux-64, osx-64, win-64
r-somebm	0.1	some Brownian motions simulation functions / MIT	noarch
r-somekfw	1.2	This package collects some procedures controlling the Generalized Family-wise Error Rate. / GPL-2	noarch
r-somemtp	1.4.1	It's a collection of functions for Multiplicity Correction and Multiple Testing. / GPL-2	noarch
r-sommer	4.0.4	Structural multivariate-univariate linear mixed model solver for estimation of multiple random effects and unknown variance-covariance structures (i.e. heterogeneous and unstructured variance models) (Covarrubias-Pazarán, 2016 <doi:10.1371/journal.pone.0156744>; Maier et al., 2015 <doi:10.1016/j.ajhg.2014.12.006>). ML/REML estimates can be obtained using the Direct-Inversion Newton-Raphson and Direct-Inversion Average Information algorithms. Designed for genomic prediction and genome wide association studies (GWAS), particularly focused in the $p > n$ problem (more coefficients than observations) and dense known covariance structures for levels of random effects. Spatial models can also be fitted using i.e. the two-dimensional spline functionality available in sommer. / GPL-2	linux-64, osx-64, win-64
r-somplot	1.6.4	The package provides the plot function som.plot() to create high quality visualisations of hexagonal Kohonen maps (self-organising maps). / GPL-2	noarch
r-sonar	1.0.2	Formulas for calculating sound velocity, water pressure, depth, density, absorption and sonar equations. / GPL-3	noarch
r-soniclength	1.4.6	Estimate the abundance of cell clones from the distribution of lengths of DNA fragments (as created by sonication, whence 'sonicLength'). The algorithm in Estimating abundances of retroviral insertion sites from DNA fragment length data by Berry CC, Gillet NA, Melamed A, Gormley N, Bangham CR, Bushman FD. Bioinformatics; 2012 Mar 15;28(6):755-62 is implemented. The experimental setting and estimation details are described in detail there. Briefly, integration of new DNA in a host genome (due to retroviral infection or gene therapy) can be tracked using DNA sequencing, potentially allowing characterization of the abundance of individual cell clones bearing distinct integration sites. The locations of integration sites can be determined by fragmenting the host DNA (via sonication or fragmentase), breaking the newly integrated DNA at a known sequence, amplifying the fragments containing both host and integrated DNA, sequencing those amplicons, then mapping the host sequences to positions on the reference genome. The relative number of fragments containing a given position in the host genome estimates the relative abundance of cells hosting the corresponding integration site, but that number is not available and the count of amplicons per fragment varies widely. However, the expected number of distinct fragment lengths is a function of the abundance of cells hosting an integration site at a given position and a certain nuisance parameter. The algorithm implicitly estimates that function to estimate the relative abundance. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-soobench	1.0_7	Collection of different single objective test functions useful for benchmarks and algorithm development. / BSD	linux-64, osx-64, win-64
r-sopie	1.5	Provides functions to non-parametrically estimate the off-pulse interval of a source function originating from a pulsar. The technique is based on a sequential application of P-values obtained from goodness-of-fit tests for the uniform distribution, such as the Kolmogorov-Smirnov, Cramer-von Mises, Anderson-Darling and Rayleigh goodness-of-fit tests. / GPL-3	noarch
r-soql	0.1.1	Used to construct the URLs and parameters of ‘Socrata Open Data API’ < https://dev.socrata.com > calls, using the API’s ‘SoQL’ parameter format. Has method-chained and sensical syntax. Plays well with pipes. / MIT	noarch
r-sor	0.23.1	Estimation for longitudinal data following outcome dependent sampling using the sequential offsetted regression technique. Includes support for binary, count, and continuous data. The first regression is a logistic regression, which uses a known ratio (the probability of being sampled given that the subject/observation was referred divided by the probability of being sampled given that the subject/observation was no referred) as an offset to estimate the probability of being referred given outcome and covariates. The second regression uses this estimated probability to calculate the mean population response given covariates. / GPL-3	noarch
r-sorptionanalysis	0.1.0	Provides tools to efficiently analyze and visualize laboratory data from aqueous static adsorption experiments. The package provides functions to plot Langmuir, Freundlich, and Temkin isotherms and functions to determine the statistical conformity of data points to the Langmuir, Freundlich, and Temkin adsorption models through statistical characterization of the isothermic least squares regressions lines. Scientific Reference: Dada, A.O, Olalekan, A., Olatunya, A. (2012) <doi:10.9790/5736-0313845>. / GPL-2	noarch
r-sortablehtmltables	0.1_3	SortableHTMLTables writes a data frame to an HTML file that contains a sortable table. The sorting is done using the jQuery plugin Tablesorter. The appearance is controlled through a CSS file and several GIF’s. / MIT	noarch
r-sotkanet	0.9.48	Access data from the sotkanet open data portal < https://www.sotkanet.fi/sotkanet/fi/index >. / BSD_2_clause	noarch
r-sotu	1.0.2	The President of the United States is constitutionally obligated to provide a report known as the ‘State of the Union’. The report summarizes the current challenges facing the country and the president’s upcoming legislative agenda. While historically the State of the Union was often a written document, in recent decades it has always taken the form of an oral address to a joint session of the United States Congress. This package provides the raw text from every such address with the intention of being used for meaningful examples of text analysis in R. The corpus is well suited to the task as it is historically important, includes material intended to be read and material intended to be spoken, and it falls in the public domain. As the corpus spans over two centuries it is also a good test of how well various methods hold up to the idiosyncrasies of historical texts. Associated data about each address, such as the year, president, party, and format, are also included. / GPL-2	noarch
r-sound	1.4.5	Basic functions for dealing with wav files and sound samples. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-soundexbr	1.2	The SoundexBR package provides an algorithm for decoding names into phonetic codes, as pronounced in Portuguese. The goal is for homophones to be encoded to the same representation so that they can be matched despite minor differences in spelling. The algorithm mainly encodes consonants; a vowel will not be encoded unless it is the first letter. The soundex code resultant consists of a four digits long string composed by one letter followed by three numerical digits: the letter is the first letter of the name, and the digits encode the remaining consonants. / GPL-2	linux-64, osx-64, win-64
r-source.gist	1.0.0	Analogous to source(), but works when given a Gist URL or ID. / MIT	noarch
r-sourcetools	0.1.7	Tools for the reading and tokenization of R code. The ‘sourcetools’ package provides both an R and C interface for the tokenization of R code, and helpers for interacting with the tokenized representation of R code. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-sp	1.3_1	Classes and methods for spatial data; the classes document where the spatial location information resides, for 2D or 3D data. Utility functions are provided, e.g. for plotting data as maps, spatial selection, as well as methods for retrieving coordinates, for subsetting, print, summary, etc. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-sp23design	0.9	Provides methods for generating, exploring and executing seamless Phase II-III designs of Lai, Lavori and Shih using generalized likelihood ratio statistics. Includes pdf and source files that describe the entire R implementation with the relevant mathematical details. / LGPL-3	noarch
r-spa3g	1.0	The package implements the model-based kernel machine method for detecting gene-centric gene-gene interactions of Li and Cui (2012). / GPL-3	noarch
r-spaa	0.2.2	Miscellaneous functions for analysing species association and niche overlap. / GPL-2	noarch
r-space	0.1_1	Partial correlation estimation with joint sparse regression model / GPL-2	linux-64, osx-64, win-64
r-spacejam	1.1	This package provides an extension of conditional independence (CIG) and directed acyclic graph (DAG) estimation to the case where conditional relationships are (non-linear) additive models. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spacesrgb	1.2_2	Standard RGB spaces included are sRGB, ‘Adobe’ RGB, ‘ProPhoto’ RGB, BT.709, and others. User-defined RGB spaces are also possible. There is partial support for ACES Color workflows. / GPL-3	noarch
r-spacesxyz	1.0_4	Functions for converting among CIE XYZ, xyY, Lab, and Luv. The XYZs of some standard illuminants and some standard linear chromatic adaptation transforms (CATs) are included. Compute CCT and the Planckian and daylight loci. Three different standard color difference metrics are included. / GPL-3	noarch
r-spacyr	1.2	An R wrapper to the ‘Python’ ‘spaCy’ ‘NLP’ library, from http://spacy.io . / GPL-3	noarch
r-spaddins	0.2.0	A set of RStudio addons that are designed to be used in combination with user-defined RStudio keyboard shortcuts. These addons either: 1) insert text at a cursor position (e.g. insert operators %>%, <<-, %\$%, etc.), 2) replace symbols in selected pieces of text (e.g., convert backslashes to forward slashes which results in stings like c:dataconverted into c:/data/) or 3) enclose text with special symbols (e.g., converts bold into bold) which is convenient for editing R Markdown files. / MIT	noarch
r-spader	0.1.1	Estimation of various biodiversity indices and related (dis)similarity measures based on individual-based (abundance) data or sampling-unit-based (incidence) data taken from one or multiple communities/assemblages. / GPL-3	noarch
r-spaero	0.5.0	Implements methods for anticipating the emergence and eradication of infectious diseases from surveillance time series. Also provides support for computational experiments testing the performance of such methods. / GPL-2	noarch
r-spam	2.2_2	Set of functions for sparse matrix algebra. Differences with other sparse matrix packages are: (1) we only support (essentially) one sparse matrix format, (2) based on transparent and simple structure(s), (3) tailored for MCMC calculations within G(M)RF. (4) and it is fast and scalable (with the extension package spam64). / LGPL-2 BSD_3_clause	linux-64, osx-64, win-64
r-spam64	2.2_2	Provides the Fortran code of the R package ‘spam’ with 64-bit integers. Loading this package together with the R package spam enables the sparse matrix class spam to handle huge sparse matrices with more than 2 ³¹ -1 non-zero elements. / LGPL-2 BSD_3_clause	linux-64, osx-64, win-64
r-spanel	0.1	Fit the spatial panel data models: the fixed effects, random effects and between models. / GPL-3	noarch
r-spanish	0.4.2	Character vector to numerical translation in Euros from Spanish spelled monetary quantities. Reverse translation from integer to Spanish. Upper limit is up to the millions range. Geocoding via Cadastral web site. / GPL-3	noarch
r-spar	0.1	This package performs robust nonparametric tests for rare variants association analysis using summation of partition approaches that incorporate gene-gene and gene-environmental interactions / GPL-2	noarch
r-sparcl	1.0.4	Implements the sparse clustering methods of Witten and Tibshirani (2010): A framework for feature selection in clustering; published in Journal of the American Statistical Association 105(490): 713-726. / GPL-2	linux-64, osx-64, win-64
r-sparkline	2.0	Include interactive sparkline charts http://omnipotent.net/jquery.sparkline in all R contexts with the convenience of ‘htmlwidgets’. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sparklyr	1.0.0	R interface to Apache Spark, a fast and general engine for big data processing, see < http://spark.apache.org >. This package supports connecting to local and remote Apache Spark clusters, provides a ‘dplyr’ compatible back-end, and provides an interface to Spark’s built-in machine learning algorithms. / Apache License 2.0 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-sparkr	2.4.4	Provides an R Front end for ‘Apache Spark’ < https://spark.apache.org >. / Apache License (== 2.0)	noarch
r-sparktex	0.1	Generate syntax for use with the sparklines package for LaTeX. / GPL-2	noarch
r-sparql	1.16	Use SPARQL to pose SELECT or UPDATE queries to an end-point. / GPL-3	noarch
r-sparsebnutils	0.0.7	A set of tools for representing and estimating sparse Bayesian networks from continuous and discrete data, as described in Aragam, Gu, and Zhou (2017) <arXiv:1703.04025>. / GPL-2	noarch
r-sparsedc	0.1.17	Implements the algorithm described in Barron, M., Zhang, S. and Li, J. 2017, A sparse differential clustering algorithm for tracing cell type changes via single-cell RNA-sequencing data, Nucleic Acids Research, gkx1113, <doi:10.1093/nar/gkx1113>. This algorithm clusters samples from two different populations, links the clusters across the conditions and identifies marker genes for these changes. The package was designed for scRNA-Seq data but is also applicable to many other data types, just replace cells with samples and genes with variables. The package also contains functions for estimating the parameters for SparseDC as outlined in the paper. We recommend that users further select their marker genes using the magnitude of the cluster centers. / GPL-3	noarch
r-sparseeigen	0.1.0	Computation of sparse eigenvectors of a matrix (aka sparse PCA) with running time 2-3 orders of magnitude lower than existing methods and better final performance in terms of recovery of sparsity pattern and estimation of numerical values. Can handle covariance matrices as well as data matrices with real or complex-valued entries. Different levels of sparsity can be specified for each individual ordered eigenvector and the method is robust in parameter selection. See vignette for a detailed documentation and comparison, with several illustrative examples. The package is based on the paper: K. Benidis, Y. Sun, P. Babu, and D. P. Palomar (2016). Orthogonal Sparse PCA and Covariance Estimation via Procrustes Reformulation, IEEE Transactions on Signal Processing <doi:10.1109/TSP.2016.2605073>. / GPL-3	noarch
r-sparsegrid	0.8.2	SparseGrid is a package to create sparse grids for numerical integration, based on code from www.sparse-grids.de / GPL-3	noarch
r-sparsehessianfd	0.3.3	Estimates Hessian of a scalar-valued function, and returns it in a sparse Matrix format. The sparsity pattern must be known in advance. The algorithm is especially efficient for hierarchical models with a large number of heterogeneous units. See Braun, M. (2017) <doi:10.18637/jss.v082.i10>. / MPL (== 2.0)	linux-64, osx-64, win-64

Name	Version	Summary/License	Platforms
r-sparseindextracking	0.1.1	Computation of sparse portfolios for financial index tracking, i.e., joint selection of a subset of the assets that compose the index and computation of their relative weights (capital allocation). The level of sparsity of the portfolios, i.e., the number of selected assets, is controlled through a regularization parameter. Different tracking measures are available, namely, the empirical tracking error (ETE), downside risk (DR), Huber empirical tracking error (HETE), and Huber downside risk (HDR). See vignette for a detailed documentation and comparison, with several illustrative examples. The package is based on the paper: K. Benidis, Y. Feng, and D. P. Palomar, Sparse Portfolios for High-Dimensional Financial Index Tracking, IEEE Trans. on Signal Processing, vol. 66, no. 1, pp. 155-170, Jan. 2018. <doi:10.1109/TSP.2017.2762286>. / GPL-3	noarch
r-sparsem	1.77	Some basic linear algebra functionality for sparse matrices is provided: including Cholesky decomposition and backsolving as well as standard R subsetting and Kronecker products. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-sparsemdc	0.99.5	Implements the algorithm described in Barron, M., and Li, J. (Not yet published). This algorithm clusters samples from multiple ordered populations, links the clusters across the conditions and identifies marker genes for these changes. The package was designed for scRNA-Seq data but is also applicable to many other data types, just replace cells with samples and genes with variables. The package also contains functions for estimating the parameters for SparseMDC as outlined in the paper. We recommend that users further select their marker genes using the magnitude of the cluster centers. / GPL-3	noarch
r-sparsemse	1.2.1	Implements the routines and algorithms developed and analysed in Multiple systems estimation for Sparse Capture Data: Inferential Challenges when there are Non-Overlapping Lists Chan, L, Silverman, B. W., Vincent, K (2019) <arXiv:1902.05156>. This package explicitly handles situations where there are pairs of lists which have no observed individuals in common. / GPL-2	noarch
r-sparsemvn	0.2.1	Computes multivariate normal (MVN) densities, and samples from MVN distributions, when the covariance or precision matrix is sparse. / MPL (>= 2.0)	noarch
r-sparsepp	1.22	Provides interface to 'sparsepp' - fast, memory efficient hash map. It is derived from Google's excellent 'sparsehash' implementation. We believe 'sparsepp' provides an unparalleled combination of performance and memory usage, and will outperform your compiler's unordered_map on both counts. Only Google's 'dense_hash_map' is consistently faster, at the cost of much greater memory usage (especially when the final size of the map is not known in advance). / BSD_3_clause	noarch
r-sparsesem	2.5	Sparse-aware maximum likelihood for structural equation models in inferring gene regulatory networks / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sparsestep	1.0.0	Implements the SparseStep model for solving regression problems with a sparsity constraint on the parameters. The SparseStep regression model was proposed in Van den Burg, Groenen, and Alfons (2017) < https://arxiv.org/abs/1701.06967 >. In the model, a regularization term is added to the regression problem which approximates the counting norm of the parameters. By iteratively improving the approximation a sparse solution to the regression problem can be obtained. In this package both the standard SparseStep algorithm is implemented as well as a path algorithm which uses golden section search to determine solutions with different values for the regularization parameter. / GPL-2	noarch
r-sparsesvd	0.2	Wrapper around the ‘SVDLIBC’ library for (truncated) singular value decomposition of a sparse matrix. Currently, only sparse real matrices in Matrix package format are supported. / BSD_3_clause	linux-64, osx-64, win-64
r-sparsesvm	1.1_6	Fast algorithm for fitting solution paths of sparse SVM models with lasso or elastic-net regularization. / GPL-3	linux-64, osx-64, win-64
r-sparsio	1.0.0	Fast ‘SVMlight’ reader and writer. ‘SVMlight’ is most commonly used format for storing sparse matrices (possibly with some target variable) on disk. For additional information about ‘SVMlight’ format see < http://svmlight.joachims.org/ >. / GPL-2	linux-64, osx-64, win-64
r-spatest	3.0.0	Performs score test using saddlepoint approximation to estimate the null distribution. Also prepares summary statistics for meta-analysis and performs meta-analysis to combine multiple association results. For the latest version, please check < https://github.com/leeshawn/SPAtest >. / GPL-2	noarch
r-spatgraphs	3.2_1	Graphs (or networks) and graph component calculations for spatial locations in 1D, 2D, 3D etc. / GPL-2	linux-64, osx-64, win-64
r-spatial	7.3_1	Functions for kriging and point pattern analysis. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spatialacc	0.1_3	Provides a set of spatial accessibility measures from a set of locations (demand) to another set of locations (supply). It aims, among others, to support research on spatial accessibility to health care facilities. Includes the locations and some characteristics of major public hospitals in Greece. / GPL-2	noarch
r-spatialcovariance	0.6_9	Functions that compute the spatial covariance matrix for the matern and power classes of spatial models, for data that arise on rectangular units. This code can also be used for the change of support problem and for spatial data that arise on irregularly shaped regions like counties or zipcodes by laying a fine grid of rectangles and aggregating the integrals in a form of Riemann integration. / GPL-3	noarch
r-spatialml	0.1.3	Implements a spatial extension of the random forest algorithm (Georganos et al. (2019) <doi:10.1080/10106049.2019.1595177>). Future updates include more local machine learning methods as well as a geographically weighted random forest. / GPL-2	noarch
r-spatialnp	1.1_3	Test and estimates of location, tests of independence, tests of sphericity and several estimates of shape all based on spatial signs, symmetrized signs, ranks and signed ranks. For details, see Oja and Randles (2004) <doi:10.1214/088342304000000558> and Oja (2010) <doi:10.1007/978-1-4419-0468-3>. / GPL-2	linux-64, osx-64, win-64
r-spatialpack	0.3_8	Tools to assess the association between two spatial processes. Currently, several methodologies are implemented: A modified t-test to perform hypothesis testing about the independence between the processes, a suitable nonparametric correlation coefficient, the codispersion coefficient, and an F test for assessing the multiple correlation between one spatial process and several others. Functions for image processing and computing the spatial association between images are also provided. SpatialPack gives methods to complement methodologies that are available in geoR for one spatial process. / GPL (>= 2.0)	linux-64, osx-64, win-64
r-spatimeclus	1.0	Mixture model is used to achieve the clustering goal. Each component is itself a mixture model of polynomial autoregressive regressions whose the logistic weights consider the spatial and temporal information. / GPL-2	linux-64, osx-64, win-64
r-spatiotemporal	1.1.9	Utilities that estimate, predict and cross-validate the spatio-temporal model developed for MESA Air. / GPL-2	linux-64, osx-64, win-64
r-spatstat.utils	1.13	Contains utility functions for the ‘spatstat’ package which may also be useful for other purposes. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spbayes	0.4.2	Fits univariate and multivariate spatio-temporal random effects models for point-referenced data using Markov chain Monte Carlo (MCMC). Details are given in Finley, Banerjee, and Gelfand (2015) <doi:10.18637/jss.v063.i13> and Finley, Banerjee, and Cook (2014) <doi:10.1111/2041-210X.12189>. / GPL-2	linux-64, osx-64, win-64
r-spbsampling	1.3.0	Selection of spatially balanced samples. In particular, the implemented sampling designs allow to select probability samples well spread over the population of interest, in any dimension and using any distance function (e.g. Euclidean distance, Manhattan distance). For more details, Benedetti R and Piersimoni F (2017) <doi:10.1002/bimj.201600194> and Benedetti R and Piersimoni F (2017) <arXiv:1710.09116>. The implementation has been done in C through the use of ‘Rcpp’ and ‘RcppArmadillo’. / GPL-3	linux-64, osx-64, win-64
r-spcadjust	1.1	Calibration of thresholds of control charts such as CUSUM charts based on past data, taking estimation error into account. / GPL-2	noarch
r-spcalda	1.0	A new reduced-rank LDA method which works for high dimensional multi-class data. / GPL-2	noarch
r-spcavrp	0.4	Implements the SPCAvRP algorithm, developed and analysed in Sparse principal component analysis via random projections Gataric, M., Wang, T. and Samworth, R. J. (2018) <arXiv:1712.05630>. The algorithm is based on the aggregation of eigenvector information from carefully-selected random projections of the sample covariance matrix. / GPL-3	noarch
r-spcdanalyze	0.1.0	Programs to find the sample size or power of studies using the Sequential Parallel Comparison Design (SPCD) and programs to analyze such studies. This is a clinical trial design where patients initially on placebo who did not respond are re-randomized between placebo and active drug in a second phase and the results of the two phases are pooled. The method of analyzing binary data with this design is described in Fava, Evins, Dorer and Schoenfeld (2003) <doi:10.1159/000069738>, and the method of analyzing continuous data is described in Chen, Yang, Hung and Wang (2011) <doi:10.1016/j.cct.2011.04.006>. / Unlimited	noarch
r-spcov	1.01	Provides a covariance estimator for multivariate normal data that is sparse and positive definite. Implements the majorize-minimize algorithm described in Bien, J., and Tibshirani, R. (2011), Sparse Estimation of a Covariance Matrix, Biometrika. 98(4). 807–820. / GPL-2	noarch
r-spd	2.0.1	The Semi Parametric Piecewise Distribution blends the Generalized Pareto Distribution for the tails with a kernel based interior. / GPL-3	noarch
r-spddata	0.3.0	Diverse spatial datasets for demonstrating, benchmarking and teaching spatial data analysis. It includes R data of class sf (defined by the package ‘sf’), Spatial (‘sp’), and nb (‘spdep’). Unlike other spatial data packages such as ‘rnatuarearth’ and ‘maps’, it also contains data stored in a range of file formats including GeoJSON, ESRI Shapefile and GeoPackage. Some of the datasets are designed to illustrate specific analysis techniques. cycle_hire() and cycle_hire_osm(), for example, is designed to illustrate point pattern analysis techniques. / CC0	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-spdyscale	0.1.0	Spatial downscaling of climate data (Global Circulation Models/Regional Climate Models) using quantile-quantile bias correction technique. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spearman	1.0	Functions for conducting jackknife Euclidean / empirical likelihood inference for Spearman's rho (de Carvalho and Marques (2012) <10.1080/10920277.2012.10597644>). / GPL-3	noarch
r-spec	0.1.7	Creates a data specification that describes the columns of a table (data.frame). Provides methods to read, write, and update the specification. Checks whether a table matches its specification. See specification.data.frame(), read.spec(), write.spec(), as.csv.spec(), respecify.character(), and %matches%.data.frame(). / GPL-3	noarch
r-speccalt	0.1.1	Alternative to the kernlab::specc function. Includes a spectral clustering implementation, a locally adapted kernel function akin to what is already proposed in kernlab, and an optional procedure that automatically estimates the optimal number of clusters. Several sample data sets are also included. / LGPL-3	noarch
r-specdetec	1.0.0	Calculate change point based on spectral clustering with the option to automatically calculate the number of clusters if this information is not available. / GPL-3	noarch
r-spectralgp	1.3.3	Routines for creating, manipulating, and performing Bayesian inference about Gaussian processes in one and two dimensions using the Fourier basis approximation: simulation and plotting of processes, calculation of coefficient variances, calculation of process density, coefficient proposals (for use in MCMC). It uses R environments to store GP objects as references/pointers. / GPL-2	noarch
r-spedinstabr	1.8	From output files obtained from the software 'ModestR', the relative contribution of factors to explain species distribution is depicted using several plots. A global geographic raster file for each environmental variable may be also obtained with the mean relative contribution, considering all species present in each raster cell, of the factor to explain species distribution. Finally, for each variable it is also possible to compare the frequencies of any variable obtained in the cells where the species is present with the frequencies of the same variable in the cells of the extent. / GPL-2	noarch
r-speedglm	0.3_2	Fitting linear models and generalized linear models to large data sets by updating algorithms. / GPL-3	noarch
r-speff2trial	1.0.4	The package performs estimation and testing of the treatment effect in a 2-group randomized clinical trial with a quantitative, dichotomous, or right-censored time-to-event endpoint. The method improves efficiency by leveraging baseline predictors of the endpoint. The inverse probability weighting technique of Robins, Rotnitzky, and Zhao (JASA, 1994) is used to provide unbiased estimation when the endpoint is missing at random. / GPL-2	noarch
r-spelling	2.1	Spell checking common document formats including latex, markdown, manual pages, and description files. Includes utilities to automate checking of documentation and vignettes as a unit test during 'R CMD check'. Both British and American English are supported out of the box and other languages can be added. In addition, packages may define a 'wordlist' to allow custom terminology without having to abuse punctuation. / MIT	noarch
r-sprgrass6	0.8_9	Interpreted interface between GRASS 6 geographical information system and R, based on starting R from within the GRASS environment, or running free-standing R in a temporary GRASS location; the package provides facilities for using all GRASS commands from the R command line. This package may not be used for GRASS 7, for which rgrass7 should be used. / GPL-2	noarch
r-spherick	1.2	Spherical K-function for point-pattern analysis on the sphere. / GPL-2	noarch
r-spi	1.1	Compute the SPI index using R / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spiassay	1.1.0	The SNP Panel Identification Assay (SPIA) is a package that enables an accurate determination of cell line identity from the genotype of single nucleotide polymorphisms (SNPs). The SPIA test allows to discern when two cell lines are close enough to be called similar and when they are not. Details about the method are available at Demichelis et al. (2008) SNP panel identification assay (SPIA): a genetic-based assay for the identification of cell lines. Nucleic Acids Res., 3, 2446-2456. / GPL-2	noarch
r-spiders	1.2	Fits and simulates data from our predator preferences model, <DOI:10.1007/s10651-016-0341-3>. / GPL (>= 2.0)	noarch
r-spikes	1.1	Applies re-sampled kernel density method to detect vote fraud. It estimates the proportion of coarse vote-shares in the observed data relative to the null hypothesis of no fraud. / GPL-2	noarch
r-spin	1.1	An optimal weighting strategy to compute simulation-efficient shortest probability intervals (spins). / GPL-2	noarch
r-spina	4.1.0	Calculates constant structure parameters of endocrine homeostatic systems from equilibrium hormone concentrations. Methods and equations have been described in Dietrich et al. (2012) <doi:10.1155/2012/351864> and Dietrich et al. (2016) <doi:10.3389/fendo.2016.00057>. / BSD_3_clause	noarch
r-spinyreg	0.1_0	Implements a generative model that uses a spike-and-slab like prior distribution obtained by multiplying a deterministic binary vector. Such a model allows an EM algorithm, optimizing a type-II log-likelihood. / GPL-2	noarch
r-spirit	0.1.1	Contains an R Markdown template for a clinical trial protocol adhering to the SPIRIT statement. The SPIRIT (Standard Protocol Items for Interventional Trials) statement outlines recommendations for a minimum set of elements to be addressed in a clinical trial protocol. Also contains functions to create a xml document from the template and upload it to clinicaltrials.gov< https://www.clinicaltrials.gov/ > for trial registration. / MIT	noarch
r-splines2	0.2.8	Constructs B-splines and its integral, monotone splines (M-splines) and its integral (I-splines), convex splines (C-splines), and their derivatives of given order. Piecewise constant basis is allowed for B-splines and M-splines. See De Boor (1978) <doi:10.1002/zamm.19800600129>, Ramsay (1988) <doi:10.1214/ss/1177012761>, and Meyer (2008) <doi:10.1214/08-AOAS167> for more information. / GPL-3	noarch
r-splitfeas	0.1.0	An implementation of the majorization-minimization (MM) algorithm introduced by Xu, Chi, Yang, and Lange (2017) <arXiv:1612.05614> for solving multi-set split feasibility problems. In the multi-set split feasibility problem, we seek to find a point x in the intersection of multiple closed sets and whose image under a mapping also must fall in the intersection of several closed sets. / MIT	noarch
r-splitstackshape	1.4.8	Online data collection tools like Google Forms often export multiple-response questions with data concatenated in cells. The concat.split (cSplit) family of functions splits such data into separate cells. The package also includes functions to stack groups of columns and to reshape wide data, even when the data are unbalanced—something which reshape (from base R) does not handle, and which melt and dcast from reshape2 do not easily handle. / GPL-3	noarch
r-plot	0.5.0	Automates common plotting tasks to ease data exploration. Makes density plots (potentially overlaid on histograms), scatter plots with prediction lines, or bar or line plots with error bars. For each type, y, or x and y variables can be plotted at levels of other variables, all with minimal specification. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-spls	2.2_3	Provides functions for fitting a sparse partial least squares (SPLS) regression and classification (Chun and Keles (2010) <doi:10.1111/j.1467-9868.2009.00723.x>). / GPL-2	noarch
r-spongebob	0.4.0	Convert text (and text in R objects) to Mocking SpongeBob case < https://knowyourmeme.com/memes/mocking-spongebob > and show them off in fun ways. CoNVERt TeXt (AnD TeXt In r ObJeCtS) To MOCKINg SpoNge-bOb CAsE < https://knowyourmeme.com/memes/mocking-spongebob > aND shOW tHeM OFF IN Fun WayS. / BSD_3_clause	noarch
r-sporm	1.1	R implementation of the methods described in A rank-based empirical likelihood approach to two-sample proportional odds model and its goodness-of-fit by Zhong Guan and Cheng Peng, Journal of Nonparametric Statistics, to appear. / GPL-2	noarch
r-sportsanalytics	0.2	The aim of this package is to provide infrastructure for sports analysis. Anyway, currently it is a selection of data sets, functions to fetch sports data, examples, and demos – with the ambition to develop bit by bit a set of classes to represent general concepts of sports analysis. / GPL-2	noarch
r-spreda	1.1	The Statistical Package for REliability Data Analysis (SPREDA) implements recently-developed statistical methods for the analysis of reliability data. Modern technological developments, such as sensors and smart chips, allow us to dynamically track product/system usage as well as other environmental variables, such as temperature and humidity. We refer to these variables as dynamic covariates. The package contains functions for the analysis of time-to-event data with dynamic covariates and degradation data with dynamic covariates. The package also contains functions that can be used for analyzing time-to-event data with right censoring, and with left truncation and right censoring. Financial support from NSF and DuPont are acknowledged. / GPL-2	noarch
r-sprsmld	0.1_0	R functions to mine sparse models from data. / GPL-2	noarch
r-sprt	1.0	Perform Wald's Sequential Probability Ratio Test on variables with a Normal, Bernoulli, Exponential and Poisson distribution. Plot acceptance and continuation regions, or create your own with the help of closures. / BSD_2_clause	noarch
r-spsl	0.1_9	Provides basic functionality for labeling iso- & anisotropic percolation clusters on 2D & 3D square lattices with various lattice sizes, occupation probabilities, von Neumann & Moore (1,d)-neighborhoods, and random variables weighting the percolation lattice sites. / GPL-3	noarch
r-spurs	2.0.2	Provides functions and datasets from Jones, O.D., R. Maillardet, and A.P. Robinson. 2014. An Introduction to Scientific Programming and Simulation, Using R. 2nd Ed. Chapman And Hall/CRC. / GPL-3	noarch
r-spyvsspy	0.1.1	Data on the Spy vs. Spy comic strip of Mad magazine, created and written by Antonio Prohias. / LGPL-3	noarch
r-sqlrender	1.6.2	A rendering tool for parameterized SQL that also translates into different SQL dialects. These dialects include 'Microsoft Sql Server', 'Oracle', 'PostgreSql', 'Amazon RedShift', 'Apache Impala', 'IBM Netezza', 'Google BigQuery', 'Microsoft PDW', and 'SQLite'. / Apache License 2.0	noarch
r-sqlutils	1.2	This package provides utilities for working with a library of SQL files. / GPL-3	noarch
r-sqrl	0.6.3	Facilitates interaction with ODBC data sources by managing communications on behalf of the user. Supports multi-statement SQL scripts, with or without embedded R. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-squarem	2017.10	Algorithms for accelerating the convergence of slow, monotone sequences from smooth, contraction mapping such as the EM algorithm. It can be used to accelerate any smooth, linearly convergent acceleration scheme. A tutorial style introduction to this package is available in a vignette on the CRAN download page or, when the package is loaded in an R session, with vignette(SQUAREM). / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-squash	1.0.8	Functions for color-based visualization of multivariate data, i.e. colorgrams or heatmaps. Lower-level functions map numeric values to colors, display a matrix as an array of colors, and draw color keys. Higher-level plotting functions generate a bivariate histogram, a dendrogram aligned with a color-coded matrix, a triangular distance matrix, and more. / Artistic-2.0	noarch
r-sra	0.1.1	This package (sra) provides a set of tools to analyse artificial-selection response datasets. The data typically feature for several generations the average value of a trait in a population, the variance of the trait, the population size and the average value of the parents that were chosen to breed. Sra implements two families of models aiming at describing the dynamics of the genetic architecture of the trait during the selection response. The first family relies on purely descriptive (phenomenological) models, based on an autoregressive framework. The second family provides different mechanistic models, accounting e.g. for inbreeding, mutations, genetic and environmental canalization, or epistasis. The parameters underlying the dynamics of the time series are estimated by maximum likelihood. The sra package thus provides (i) a wrapper for the R functions mle() and optim() aiming at fitting in a convenient way a predetermined set of models, and (ii) some functions to plot and analyze the output of the models. / GPL-2	noarch
r-srccs	1.1	Implementation of the SRCS method for a color-based visualization of the results of multiple pairwise tests on a large number of problem configurations, proposed in: I.G. del Amo, D.A. Pelta. SRCS: a technique for comparing multiple algorithms under several factors in dynamic optimization problems. In: E. Alba, A. Nakib, P. Siarry (Eds.), Metaheuristics for Dynamic Optimization. Series: Studies in Computational Intelligence 433, Springer, Berlin/Heidelberg, 2012. / LGPL-3	noarch
r-srda	1.0.0	Sparse redundancy analysis for high dimensional (biomedical) data. Directional multivariate analysis to express the maximum variance in the predicted data set by a linear combination of variables of the predictive data set. Implemented in a partial least squares framework, for more details see Csala et al. (2017) <doi:10.1093/bioinformatics/btx374>. / MIT	noarch
r-srttools	1.2.0	Srt file is a common subtitle format for videos, it contains subtitle and when the subtitle showed. This package is for align time of srt file, and also change color, style and position of subtitle in videos, the srt file will be read as a vector into R, and can be write into srt file after modified using this package. / GPL-2	noarch
r-ssanv	1.1	A set of functions to calculate sample size for two-sample difference in means tests. Does adjustments for either nonadherence or variability that comes from using data to estimate parameters. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-ssbtools	0.4.0	Functions used by other packages from Statistics Norway are gathered. General data manipulation functions, and functions for hierarchical computations are included. The hierarchy specification functions are useful within statistical disclosure control. / Apache License 2.0 file LICENSE	noarch
r-sscor	0.2	Provides the spatial sign correlation and the two-stage spatial sign correlation as well as a one-sample test for the correlation coefficient. / GPL-2 GPL-3	noarch
r-ssd	0.3	ssd calculates the sample size needed to detect the differences between two sets of unordered categorical data. / GPL-2	noarch
r-ssdr	1.2.0	Performs structured OLS (sOLS) and structured SIR (sSIR). / GPL-2	noarch
r-sse	0.7_1	Provides functions to evaluate user-defined power functions for a parameter range, and draws a sensitivity plot. It also provides a resampling procedure for semi-parametric sample size estimation and methods for adding information to a Sweave report. / GPL-3	noarch
r-ssh.utils	1.0	This package provides utility functions for system command execution, both locally and remotely using ssh/scp. The command output is captured and provided to the caller. This functionality is intended to streamline calling shell commands from R, retrieving and using their output, while instrumenting the calls with appropriate error handling. NOTE: this first version is limited to unix with local and remote systems running bash as the default shell. / Apache License (== 2.0)	linux-64
r-ssize.fdr	1.2	This package contains a set of functions that calculates appropriate sample sizes for one-sample t-tests, two-sample t-tests, and F-tests for microarray experiments based on desired power while controlling for false discovery rates. For all tests, the standard deviations (variances) among genes can be assumed fixed or random. This is also true for effect sizes among genes in one-sample and two sample experiments. Functions also output a chart of power versus sample size, a table of power at different sample sizes, and a table of critical test values at different sample sizes. / GPL-3	noarch
r-ssm	1.0.1	Creates an S4 class SSM and defines functions for fitting smooth supersaturated models, a polynomial model with spline-like behaviour. Functions are defined for the computation of Sobol indices for sensitivity analysis and plotting the main effects using FANOVA methods. It also implements the estimation of the SSM metamodel error using a GP model with a variety of defined correlation functions. / GPL-3	noarch
r-sss	0.1_0	Tools to import survey files in the .sss (triple-s) format. The package provides the function read.sss() that reads the .asc (or .csv) and .sss files of a triple-s survey data file. / GPL-2 GPL-3	noarch
r-sssimple	0.6.4	Simulate, solve state space models / GPL-2	noarch
r-ssvd	1.0	Fast iterative thresholding sparse SVD, together with an initialization algorithm / GPL-2	noarch
r-stabledist	0.7_1	Density, Probability and Quantile functions, and random number generation for (skew) stable distributions, using the parametrizations of Nolan. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-stableestim	2.1	Estimate the four parameters of stable laws using maximum likelihood method, generalised method of moments with finite and continuum number of points, iterative Koutrouvelis regression and Kogon-McCulloch method. The asymptotic properties of the estimators (covariance matrix, confidence intervals) are also provided. / GPL-2	noarch
r-stabm	1.1.0	An implementation of many measures for the assessment of the stability of feature selection. Both simple measures and measures which take into account the similarities between features are available, see Bommert et al. (2017) <doi:10.1155/2017/7907163>. / LGPL-3	noarch
r-stabs	0.6.3	Resampling procedures to assess the stability of selected variables with additional finite sample error control for high-dimensional variable selection procedures such as Lasso or boosting. Both, standard stability selection (Meinshausen & Bühlmann, 2010, <doi:10.1111/j.1467-9868.2010.00740.x>) and complementary pairs stability selection with improved error bounds (Shah & Samworth, 2013, <doi:10.1111/j.1467-9868.2011.01034.x>) are implemented. The package can be combined with arbitrary user specified variable selection approaches. / GPL-2	noarch
r-stackoverflow	0.3.0	Helper functions collected from StackOverflow.com, a question and answer site for professional and enthusiast programmers. / CC BY-SA 4.0	noarch
r-stacomirtools	0.5.3	S4 class wrappers for the ‘ODBC’ connection, also provides some utilities to paste small datasets to clipboard, rename columns. It is used by the package ‘stacomir’ for connections to the database. Development versions of ‘stacomir’ are available in R-forge. / GPL-2	noarch
r-stagedchoicesplinemix	1.0.0	Analyzing a mixture of two-stage logistic regressions with fixed candidate knots. See Bruch, E., F. Feinberg, K. Lee (in press)<DOI:10.1073/pnas.1522494113>. / GPL-2	noarch
r-stakeholderanalysis	1.2	Proposes an original instrument for measuring stakeholder influence on the development of an infrastructure project that is carried through by a municipality, drawing on stakeholder classifications (Mitchell, Agle, & Wood, 1997) and input-output modelling (Hester & Adams, 2013). Mitchell R., Agle B.R., & Wood D.J. <doi:10.2307/259247> Hester, P.T., & Adams, K.M. (2013) <doi:10.1016/j.procs.2013.09.282>. / GPL-2	noarch
r-stand	2.0	Provides functions for the analysis of occupational and environmental data with non-detects. Maximum likelihood (ML) methods for censored log-normal data and non-parametric methods based on the product limit estimate (PLE) for left censored data are used to calculate all of the statistics recommended by the American Industrial Hygiene Association (AIHA) for the complete data case. Functions for the analysis of complete samples using exact methods are also provided for the lognormal model. Revised from 2007-11-05 ‘survfit~1’. / GPL-2	noarch
r-standardize	0.2.1	Tools which allow regression variables to be placed on similar scales, offering computational benefits as well as easing interpretation of regression output. / GPL-3	noarch
r-standardizetext	1.0	Standardizes text according to a template; particularly useful for country names. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-stanheaders	2.18.1	The C header files of the Stan project are provided by this package, but it contains no R code, vignettes, or function documentation. There is a shared object containing part of the 'CVODES' library, but it is not accessible from R. 'StanHeaders' is only useful for developers who want to utilize the 'LinkingTo' directive of their package's DESCRIPTION file to build on the Stan library without incurring unnecessary dependencies. The Stan project develops a probabilistic programming language that implements full or approximate Bayesian statistical inference via Markov Chain Monte Carlo or 'variational' methods and implements (optionally penalized) maximum likelihood estimation via optimization. The Stan library includes an advanced automatic differentiation scheme, 'templated' statistical and linear algebra functions that can handle the automatically 'differentiable' scalar types (and doubles, 'ints', etc.), and a parser for the Stan language. The 'rstan' package provides user-facing R functions to parse, compile, test, estimate, and analyze Stan models. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-staplr	2.9.0	Provides function to manipulate PDF files: fill out PDF forms; merge multiple PDF files into one; remove selected pages from a file; rename multiple files in a directory; rotate entire pdf document; rotate selected pages of a pdf file; Select pages from a file; splits single input PDF document into individual pages; splits single input PDF document into parts from given points. / GPL-3	noarch
r-stargazer	5.2.2	Produces LaTeX code, HTML/CSS code and ASCII text for well-formatted tables that hold regression analysis results from several models side-by-side, as well as summary statistics. / GPL-2	noarch
r-startup	0.12.0	Adds support for R startup configuration via '.Renviron.d' and '.Rprofile.d' directories in addition to '.Renviron' and '.Rprofile' files. This makes it possible to keep private / secret environment variables separate from other environment variables. It also makes it easier to share specific startup settings by simply copying a file to a directory. / LGPL-2.1	noarch
r-startupmsg	0.9.6	Provides utilities to create or suppress start-up messages. / LGPL-3	noarch
r-stat2data	2.0.0	Datasets for the textbook Stat2: Modeling with Regression and ANOVA (second edition). The package also includes data for the first edition, Stat2: Building Models for a World of Data and a few functions for plotting diagnostics. / GPL-3	noarch
r-statdataml	1.0_26	Support for reading and writing files in StatDataML—an XML-based data exchange format. / GPL-2	noarch
r-statgraph	0.2.0	Contains statistical methods to analyze graphs, such as graph parameter estimation, model selection based on the GIC (Graph Information Criterion), statistical tests to discriminate two or more populations of graphs (ANOGVA -Analysis of Graph Variability), correlation between graphs, and clustering of graphs. / GPL-3	noarch
r-statmeasures	1.0	Offers useful functions to perform day-to-day data manipulation operations, data quality checks and post modelling statistical checks. One can effortlessly change class of a number of variables to factor, remove duplicate observations from the data, create deciles of a variable, perform data quality checks for continuous (integer or numeric), categorical (factor) and date variables, and compute goodness of fit measures such as auc for statistical models. The functions are consistent for objects of class 'data.frame' and 'data.table', which is an enhanced 'data.frame' implemented in the package 'data.table'. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-statpermeco	0.1.0	Statistical performance measures used in the econometric literature to evaluate conditional covariance/correlation matrix estimates (MSE, MAE, Euclidean distance, Frobenius distance, Stein distance, asymmetric loss function, eigenvalue loss function and the loss function defined in Eq. (4.6) of Engle et al. (2016) <doi:10.2139/ssrn.2814555>). Additionally, compute Eq. (3.1) and (4.2) of Li et al. (2016) <doi:10.1080/07350015.2015.1092975> to compare the factor loading matrix. The statistical performance measures implemented have been previously used in, for instance, Laurent et al. (2012) <doi:10.1002/jae.1248>, Amendola et al. (2015) <doi:10.1002/for.2322> and Becker et al. (2015) <doi:10.1016/j.ijforecast.2013.11.007>. / GPL-2	noarch
r-statprograms	0.2.0	A small collection of data on graduate statistics programs from the United States. / MIT	noarch
r-stcov	0.1.0	Estimates a covariance matrix using Stein's isotonized covariance estimator, or a related estimator suggested by Haff. / GPL-2	noarch
r-stddiff	2.0	Contains three main functions including stddiff.numeric(), stddiff.binary() and stddiff.category(). These are used to calculate the standardized difference between two groups. It is especially used to evaluate the balance between two groups before and after propensity score matching. / GPL-3	noarch
r-steinernet	3.0.1	A set of functions for finding and analysing Steiner trees. It has applications in biological pathway network analysis. Sadeghi (2013) <doi:10.1186/1471-2105-14-144>. / GPL-3	noarch
r-steiniv	0.1.1	Routines for computing different types of linear estimators, based on instrumental variables (IVs), including the semi-parametric Stein-like (SPS) estimator, originally introduced by Judge and Mittelhammer (2004) <DOI:10.1198/016214504000000430>. / GPL-2	noarch
r-stellar	0.3.3	A package to manage and display stellar tracks and isochrones from Pisa low-mass database. Includes tools for isochrones construction and tracks interpolation. / GPL-2	noarch
r-stem	1.0	Estimation of the parameters of a spatio-temporal model using the EM algorithm, estimation of the parameter standard errors using a spatio-temporal parametric bootstrap, spatial mapping. / GPL-2	noarch
r-stemmatology	0.3.2	Explore and analyse the genealogy of textual or musical traditions, from their variants, with various stemmatological methods, mainly the disagreement-based algorithms suggested by Camps and Cafiero (2015) <doi:10.1484/M.LECTIO-EB.5.102565>. / GPL-3	noarch
r-stevedore	0.9.1	Work with containers over the Docker API. Rather than using system calls to interact with a docker client, using the API directly means that we can receive richer information from docker. The interface in the package is automatically generated using the 'OpenAPI' (a.k.a., 'swagger') specification, and all return values are checked in order to make them type stable. / MIT	noarch
r-theoreme	1.2	Functions implementing the procedure of entropy comparison between two data samples after the renormalization of respective probability distributions with the algorithm designed by Klimontovich (Zeitschrift fur Physik B Condensed Matter. 1987, Volume 66, Issue 1, pp 125-127) and extended by Anishchenko (Proc. SPIE 2098, Computer Simulation in Nonlinear Optics. 1994, pp.130-136). The package also includes data preparation tools which can also be used separately for various applications. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sticky	0.5.2	In base R, object attributes are lost when objects are modified by common data operations such as subset, filter, slice, append, extract etc. This packages allows objects to be marked as ‘sticky’ and have attributes persisted during these operations or when inserted into or extracted from recursive (i.e. list- or table-like) objects. / GPL-2	noarch
r-stinepack	1.4	A consistently well behaved method of interpolation based on piecewise rational functions using Stineman’s algorithm. / GPL-2	noarch
r-stmgp	1.0.1	Rapidly build accurate genetic prediction models for genome-wide association or whole-genome sequencing study data by smooth-threshold multivariate genetic prediction (STMGP) method. Variable selection is performed using marginal association test p-values with an optimal p-value cut-off selected by Cp-type criterion. Quantitative and binary traits are modeled respectively via linear and logistic regression models. A function that works through PLINK software (Purcell et al. 2007 <DOI:10.1086/519795>, Chang et al. 2015 <DOI:10.1186/s13742-015-0047-8>) < https://www.cog-genomics.org/plink2 > is provided. Covariates can be included in regression model. / GPL-2	noarch
r-stochprofml	1.2	This is an R package accompanying the paper Parameterizing cell-to-cell regulatory heterogeneities via stochastic transcriptional profiles by Sameer S Bajikar, Christiane Fuchs, Andreas Roller, Fabian J Theis and Kevin A Janes (PNAS 2014, 111(5), E626-635). In this paper, we measure expression profiles from small heterogeneous populations of cells, where each cell is assumed to be from a mixture of lognormal distributions. We perform maximum likelihood estimation in order to infer the mixture ratio and the parameters of these lognormal distributions from the cumulated expression measurements. / GPL-2	noarch
r-stockchina	0.3.1	With this package, users can obtain the real-time price and volume information of stocks in China market, as well as the information of the stock index. This package adopted the API from Sina Finance (http://finance.sina.com.cn/). / GPL-2	noarch
r-stoichcalc	1.1_3	Given a list of substance compositions, a list of substances involved in a process, and a list of constraints in addition to mass conservation of elementary constituents, the package contains functions to build the substance composition matrix, to analyze the uniqueness of process stoichiometry, and to calculate stoichiometric coefficients if process stoichiometry is unique. (See Reichert, P. and Schuwirth, N., A generic framework for deriving process stoichiometry in enviromental models, Environmental Modelling and Software 25, 1241-1251, 2010 for more details.) / GPL-2	noarch
r-stopos	0.1	A variable selection procedure for low to moderate size linear regressions models. This method repeatedly splits the data into two sets, one for estimation and one for validation, to obtain an empirically optimized threshold which is then used to screen for variables to include in the final model. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-stopwords	0.9.0	Provides multiple sources of stopwords, for use in text analysis and natural language processing. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-storr	1.2.1	Creates and manages simple key-value stores. These can use a variety of approaches for storing the data. This package implements the base methods and support for file system, in-memory and DBI-based database stores. / MIT	noarch
r-strategy	1.0.1	Users can build and test customized quantitative trading strategies. Some quantitative trading strategies are already implemented, e.g. various moving-average filters with trend following approaches. The implemented class called Strategy allows users to access several methods to analyze performance figures, plots and backtest the strategies. Furthermore, custom strategies can be added, a generic template is available. The custom strategies require a certain input and output so they can be called from the Strategy-constructor. / GPL-3	noarch
r-stratifiedbalancing	0.3.0	Performs Stratified Covariate Balancing with Markov blanket feature selection and use of synthetic cases. See Alemi et al. (2016) <DOI:10.1111/1475-6773.12628>. / GPL-2	noarch
r-streammetabolism	1.1.2	I provide functions to calculate Gross Primary Productivity, Net Ecosystem Production, and Ecosystem Respiration from single station diurnal Oxygen curves. / GPL-3	noarch
r-stressr	1.0.0	Forms queries to submit to the Cleveland Federal Reserve Bank web site's financial stress index data site. Provides query functions for both the composite stress index and the components data. By default the download includes daily time series data starting September 25, 1991. The functions return a class of either type easing or cfsi which contain a list of items related to the query and its graphical presentation. The list includes the time series data as an xts object. The package provides four lattice time series plots to render the time series data in a manner similar to the bank's own presentation. / MIT	noarch
r-stressstrength	1.0.2	Reliability of (normal) stress-strength models and for building two-sided or one-sided confidence intervals according to different approximate procedures. / GPL-3	noarch
r-string2adjmatrix	0.1.0	Takes a list of character strings and forms an adjacency matrix for the times the specified characters appear together in the strings provided. For use in social network analysis and data wrangling. Simple package, comprised of three functions. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-stringb	0.1.13	Base R already ships with string handling capabilities ‘out- of-the-box’ but lacks streamlined function names and workflow. The ‘stringi’ (‘stringr’) package on the other hand has well named functions, extensive Unicode support and allows for a streamlined workflow. On the other hand it adds dependencies and regular expression interpretation between base R functions and ‘stringi’ functions might differ. This packages aims at providing a solution to the use case of unwanted dependencies on the one hand but the need for streamlined text processing on the other. The packages’ functions are solely based on wrapping base R functions into ‘stringr’/‘stringi’ like function names. Along the way it adds one or two extra functions and last but not least provides all functions as generics, therefore allowing for adding methods for other text structures besides plain character vectors. / MIT	noarch
r-stringdist	0.9.5	Implements an approximate string matching version of R’s native ‘match’ function. Can calculate various string distances based on edits (Damerau-Levenshtein, Hamming, Levenshtein, optimal sting alignment), qgrams (q-gram, cosine, jaccard distance) or heuristic metrics (Jaro, Jaro-Winkler). An implementation of soundex is provided as well. Distances can be computed between character vectors while taking proper care of encoding or between integer vectors representing generic sequences. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-stringformatt	0.1.2	Pass named and unnamed character vectors into specified positions in strings. This represents an attempt to replicate some of python’s string formatting. / MIT	noarch
r-stringi	1.4.3	Allows for fast, correct, consistent, portable, as well as convenient character string/text processing in every locale and any native encoding. Owing to the use of the ICU library, the package provides R users with platform-independent functions known to Java, Perl, Python, PHP, and Ruby programmers. Available features include: pattern searching (e.g., with ICU Java-like regular expressions or the Unicode Collation Algorithm), random string generation, case mapping, string transliteration, concatenation, Unicode normalization, date-time formatting and parsing, etc. / file LICENSE (FOSS)	linux-32, linux-64, osx-64, win-32, win-64
r-stringr	1.4.0	A consistent, simple and easy to use set of wrappers around the fantastic ‘stringi’ package. All function and argument names (and positions) are consistent, all functions deal with NA’s and zero length vectors in the same way, and the output from one function is easy to feed into the input of another. / GPL-2 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-strip	1.0.0	The strip function deletes components of R model outputs that are useless for specific purposes, such as predict[ing], print[ing], summary[izing], etc. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-stripless	1.0.3	For making Trellis-type conditioning plots without strip labels. This is useful for displaying the structure of results from factorial designs and other studies when many conditioning variables would clutter the display with layers of redundant strip labels. Settings of the variables are encoded by layout and spacing in the trellis array and decoded by a separate legend. The functionality is implemented by a single S3 generic strucplot() function that is a wrapper for the Lattice package's xyplot() function. This allows access to all Lattice graphics capabilities in the usual way. / GPL-2 GPL-3	noarch
r-strucchange	1.5.1	Testing, monitoring and dating structural changes in (linear) regression models. strucchange features tests/methods from the generalized fluctuation test framework as well as from the F test (Chow test) framework. This includes methods to fit, plot and test fluctuation processes (e.g., CUSUM, MOSUM, recursive/moving estimates) and F statistics, respectively. It is possible to monitor incoming data online using fluctuation processes. Finally, the breakpoints in regression models with structural changes can be estimated together with confidence intervals. Emphasis is always given to methods for visualizing the data. / GPL-2 GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-structfdr	1.3	Perform more powerful false discovery control (FDR) for microbiome data, taking into account the prior phylogenetic relationship among bacteria species. As a general methodology, it is applicable to any type of (genomic) data with prior structure information. / GPL-2	noarch
r-stsm.class	1.3	This package defines an S4 class for structural time series models and provides some basic methods to work with it. / GPL-2	noarch
r-stuart	0.8.0	Construct subtests from a pool of items by using ant-colony-optimization, genetic algorithms, brute force, or random sampling. Schultze (2017) <doi:10.17169/refubium-622>. / GPL-3	noarch
r-stubthat	1.2.1	Create stubs of functions for use while testing. / MIT	noarch
r-stv	1.0.1	Implementations of the Single Transferable Vote counting system. By default, it uses the Cambridge method for surplus allocation and Droop method for quota calculation. Fractional surplus allocation and the Hare quota are available as options. / LGPL-3	noarch
r-stylest	0.1.0	Estimates distinctiveness in speakers' (authors') style. Fits models that can be used for predicting speakers of new texts. Methods developed in Spirling et al (2018) <doi:10.2139/ssrn.3235506> (working paper). / GPL-3	noarch
r-subcopem2d	1.3	Calculate empirical subcopula and dependence measures from a given bivariate sample, and Bernstein copula approximations. / GPL-3	noarch
r-subcultcon	1.0	The three functions in the package compute the maximum likelihood estimates of the informants' competence scores, tests for two answer keys with known groups, and finds best split of the informants into sub-culture groups. / GPL-2 GPL-3	noarch
r-subdetect	1.1	A test for the existence of a subgroup with enhanced treatment effect. And, a sample size calculation procedure for the subgroup detection test. / GPL-3	noarch
r-subgroup	1.1	Produces various measures of expected treatment effect heterogeneity under an assumption of homogeneity across subgroups. Graphical presentations are created to compare these expected differences with the observed differences. / GPL-2 GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-subgroup.discovery	0.2.1	Developed to assist in discovering interesting subgroups in high-dimensional data. The PRIM implementation is based on the 1998 paper Bump hunting in high-dimensional data by Jerome H. Friedman and Nicholas I. Fisher. <doi:10.1023/A:1008894516817> PRIM involves finding a set of rules which combined imply unusually large (or small) values of some other target variable. Specifically one tries to find a set of sub regions in which the target variable is substantially larger than overall mean. The objective of bump hunting in general is to find regions in the input (attribute/feature) space with relatively high (low) values for the target variable. The regions are described by simple rules of the type if: condition-1 and ... and condition-n then: estimated target value. Given the data (or a subset of the data), the goal is to produce a box B within which the target mean is as large as possible. There are many problems where finding such regions is of considerable practical interest. Often these are problems where a decision maker can in a sense choose or select the values of the input variables so as to optimize the value of the target variable. In bump hunting it is customary to follow a so-called covering strategy. This means that the same box construction (rule induction) algorithm is applied sequentially to subsets of the data. / GPL-3	noarch
r-subgxe	0.9.0	Classical methods for combining summary data from genome-wide association studies (GWAS) only use marginal genetic effects and power can be compromised in the presence of heterogeneity. ‘subgxe’ is a R package that implements p-value assisted subset testing for association (pASTA), a method developed by Yu et al. (2019) <doi:10.1159/000496867>. pASTA generalizes association analysis based on subsets by incorporating gene-environment interactions into the testing procedure. / GPL-3	noarch
r-subniche	0.9.7	Complementary indexes calculation to the Outlying Mean Index analysis to explore niche shift of a community and biological constraint within an Euclidean space, with graphical displays. / GPL-2	noarch
r-subpathwaygmir	1.0	Routines for identifying metabolic subpathways mediated by microRNAs (miRNAs) through topologically locating miRNAs and genes within reconstructed Kyoto Encyclopedia of Genes and Genomes (KEGG) metabolic pathway graphs embedded by miRNAs. (1) This package can obtain the reconstructed KEGG metabolic pathway graphs with genes and miRNAs as nodes, through converting KEGG metabolic pathways to graphs with genes as nodes and compounds as edges, and then integrating miRNA-target interactions verified by low-throughput experiments from four databases (TarBase, miRecords, mirTarBase and miR2Disease) into converted pathway graphs. (2) This package can locate metabolic subpathways mediated by miRNAs by topologically analyzing the lenient distance of miRNAs and genes within reconstructed KEGG metabolic pathway graphs.(3) This package can identify significantly enriched miRNA-mediated metabolic subpathways based on located subpathways by hypergenomic test. (4) This package can support six species for metabolic subpathway identification, such as caenorhabditis elegans, drosophila melanogaster, danio rerio, homo sapiens, mus musculus and rattus norvegicus, and user only need to update interested organism-specific environment variables. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-subsamp	0.1.0	This subsample winner algorithm (SWA) for regression with a large-p data (X, Y) selects the important variables (or features) among the p features X in explaining the response Y. The SWA first uses a base procedure, here a linear regression, on each of subsamples randomly drawn from the p variables, and then computes the scores of all features, i.e., the p variables, according to the performance of these features collected in each of the subsample analyses. It then obtains the ‘semifinalist’ of the features based on the resulting scores and determines the ‘finalists’, i.e., the important features, from the ‘semifinalist’. Fan, Sun and Qiao (2017) < http://sr2c.case.edu/swa-reg/ >. / GPL-2 GPL-3	noarch
r-sudoku	2.6	Generates, plays, and solves Sudoku puzzles. The GUI playSudoku() needs package tkrplot if you are not on Windows. / GPL-3	noarch
r-sudokualt	0.2.0	Tools for making, retrieving, displaying and solving sudoku games. This package is an alternative to the earlier sudoku-solver package, ‘sudoku’. The present package uses a slightly different algorithm, has a simpler coding and presents a few more sugar tools, such as plot and print methods. Solved sudoku games are of some interest in Experimental Design as examples of Latin Square designs with additional balance constraints. / GPL-2	noarch
r-sue	1.0	This is a package for the subsampling method of robust estimation of linear regression models / GPL-2	noarch
r-suncalc	0.5.0	Get sun position, sunlight phases (times for sunrise, sunset, dusk, etc.), moon position and lunar phase for the given location and time. Most calculations are based on the formulas given in Astronomy Answers articles about position of the sun and the planets : < https://www.aa.quae.nl/en/reken/zonpositie.html >. / GPL-2	noarch
r-sunclarco	1.0.0	Survival analysis for unbalanced clusters using Archimedean copulas (Prenen et al. (2016) <DOI:10.1111/rssb.12174>). / GPL-3	noarch
r-suntersampling	1.0.1	Functions for drawing samples according to Sunter’s sampling design, and for computing first and second order inclusion probabilities / GPL-3	noarch
r-supcluster	1.0	Clusters features under the assumption that each cluster has a random effect and there is an outcome variable that is related to the random effects by a linear regression. In this way the cluster analysis is “supervised” by the outcome variable. An alternate specification is that features in each cluster have the same compound symmetric normal distribution, and the conditional distribution of the outcome given the features has the same coefficient for each feature in a cluster. / GPL-2	noarch
r-superdiag	1.1	A Comprehensive Test Suite for Markov Chain Nonconvergence. / GPL-3	noarch
r-supermds	1.0.2	Witten and Tibshirani (2011) Supervised multidimensional scaling for visualization, classification, and bipartite ranking. Computational Statistics and Data Analysis 55(1): 789-801. / GPL-2	noarch
r-supernova	2.0.0	Produces ANOVA tables in the format used by Judd, McClelland, and Ryan (2017, ISBN:978-1138819832) in their introductory textbook, Data Analysis. This includes proportional reduction in error and formatting to improve ease the transition between the book and R. / GPL-3	noarch
r-superpc	1.09	Supervised principal components for regression and survival analysis. Especially useful for high-dimensional data, including microarray data. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-suppdist	1.1_9.4	Ten distributions supplementing those built into R. Inverse Gauss, Kruskal-Wallis, Kendall's Tau, Friedman's chi squared, Spearman's rho, maximum F ratio, the Pearson product moment correlation coefficient, Johnson distributions, normal scores and generalized hypergeometric distributions. In addition two random number generators of George Marsaglia are included. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-support.bws	0.2_0	Provides three basic functions that support an implementation of object case (Case 1) best-worst scaling: one for converting a two-level orthogonal main-effect design/balanced incomplete block design into questions; one for creating a data set suitable for analysis; and one for calculating count-based scores. / GPL-2	noarch
r-support.bws2	0.2_2	Provides three basic functions that support an implementation of Case 2 (profile case) best-worst scaling. The first is to convert an orthogonal main-effect design into questions, the second is to create a dataset suitable for analysis, and the third is to calculate count-based scores. / GPL-2	noarch
r-surrogateoutcome	1.0	Provides functions to estimate the proportion of treatment effect on a censored primary outcome that is explained by the treatment effect on a censored surrogate outcome/event. All methods are described in detail in Assessing the Value of a Censored Surrogate Outcome by Parast L, Tian L, and Cai T which is currently in press at Lifetime Data Analysis. The main functions are (1) R.q.event() which calculates the proportion of the treatment effect (the difference in restricted mean survival time at time t) explained by surrogate outcome information observed up to a selected landmark time, (2) R.t.estimate() which calculates the proportion of the treatment effect explained by primary outcome information only observed up to a selected landmark time, and (3) IV.event() which calculates the incremental value of the surrogate outcome information. / GPL-3	noarch
r-surrogatetest	1.1	Provides functions to test for a treatment effect in terms of the difference in survival between a treatment group and a control group using surrogate marker information obtained at some early time point in a time-to-event outcome setting. Nonparametric kernel estimation is used to estimate the test statistic and perturbation resampling is used for variance estimation. More details will be available in the future in: Parast L, Cai T, Tian L (2019). Using a Surrogate Marker for Early Testing of a Treatment Effect. Biometrics, In press. / GPL-3	noarch
r-surrosurvroc	0.1.0	Nonparametric and semiparametric estimations of the time-dependent ROC curve for an incomplete failure time data with surrogate failure time endpoints. / GPL-2	noarch
r-surtex	0.9	suRtex was designed for easy descriptive statistic reporting of categorical survey data (e.g., Likert scales) in LaTeX. suRtex takes a matrix or data frame and produces the LaTeX code necessary for a sideways table creation. Mean, median, standard deviation, and sample size are optional. / GPL-3	noarch
r-survawkmt2	1.0.0	Tests for equality of two survival functions based on integrated weighted differences of two Kaplan-Meier curves. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-survbootoutliers	1.0	Three new methods to perform outlier detection in a survival context. In total there are six methods provided, the first three methods are traditional residual-based outlier detection methods, the second three are the concordance-based. Package developed during the work on the two following publications: Pinto J., Carvalho A. and Vinga S. (2015) <doi:10.5220/0005225300750082>; Pinto J.D., Carvalho A.M., Vinga S. (2015) <doi:10.1007/978-3-319-27926-8_22>. / GPL-2	noarch
r-survexp.fr	1.0	Relative survival, AER and SMR based on French death rates / GPL-2	noarch
r-surveyeditor	1.0	Help generate slides for surveys or experiments. The resulted slides allow the subject to respond with the use of the mouse (usual keyboard input is replaced with clicking on a virtual keyboard on the slide). Subjects' responses are saved to the user- specified location in the form of R-readable text file. To allow flexibility, each function in this package generates a particular type of slides thus general R function writing skills are required to compile these edited slides. / GPL-2	noarch
r-surveyoutliers	0.1	At present, the only functionality is the calculation of optimal one-sided winsorizing cutoffs. The main function is <code>optimal.onesided.cutoff.bygroup</code> . It calculates the optimal tuning parameter for one-sided winsorisation, and so calculates winsorised values for a variable of interest. See the help file for this function for more details and an example. / GPL-2 GPL-3	noarch
r-survgini	1.0	The Gini concentration test for survival data is a nonparametric test based on the Gini index for testing the equality of two survival distributions from the point of view of concentration. The package compares different nonparametric tests (asymptotic Gini test, permutation Gini test, log-rank test, Gray-Tsiatis test and Wilcoxon test) and computes their p-values. / GPL-2	noarch
r-survival	2.44	Contains the core survival analysis routines, including definition of Surv objects, Kaplan-Meier and Aalen-Johansen (multi-state) curves, Cox models, and parametric accelerated failure time models. / LGPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-survjamda.data	1.0.2	Three breast cancer gene expression data sets that can be used for package 'survJamda'. This package contains the gene expression and phenotype data of GSE1992, GSE3143 and GSE4335. / GPL-2	noarch
r-survlong	1.0	Kernel weighting methods for estimation of proportional hazards models with intermittently observed longitudinal covariates. / GPL-2	noarch
r-survregcenscov	1.4	The main function of this package allows estimation of a Weibull Regression for a right-censored endpoint, one interval-censored covariate, and an arbitrary number of non-censored covariates. Additional functions allow to switch between different parametrizations of Weibull regression used by different R functions, inference for the mean difference of two arbitrarily censored Normal samples, and estimation of canonical parameters from censored samples for several distributional assumptions. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-survrm2	1.0_2	Performs two-sample comparisons using the restricted mean survival time (RMST) as a summary measure of the survival time distribution. Three kinds of between-group contrast metrics (i.e., the difference in RMST, the ratio of RMST and the ratio of the restricted mean time lost (RMTL)) are computed. It performs an ANCOVA-type covariate adjustment as well as unadjusted analyses for those measures. / GPL-2	noarch
r-survrm2adapt	1.0_1	Performs the procedure proposed by Horiguchi et al. (2018) <doi:10.1002/sim.7661>. The method specifies a set of truncation time points tau's for calculating restricted mean survival times (RMST), performs testing for equality, and estimates the difference in RMST between two groups at the specified tau's. Multiplicity by specifying several tau's is taken into account in this procedure. / GPL-2	noarch
r-survtrunc	0.1.0	Package performs Cox regression and survival distribution function estimation when the survival times are subject to double truncation. The estimation procedure for each method involves inverse probability weighting, where the weights correspond to the inverse of the selection probabilities and are estimated using the survival times and truncation times only. Both methods require that the survival and truncation times are quasi-independent. A test for checking this independence assumption is also included in this package. The functions available in this package for Cox regression, survival distribution function estimation, and testing independence under double truncation are based on the following methods, respectively: Rennert and Xie (2017) <doi:10.1111/biom.12809>, Shen (2010) <doi:10.1007/s10463-008-0192-2>, Martin and Betensky (2005) <doi:10.1198/016214504000001538>. / GPL-2	noarch
r-svapls	1.4	Accurate identification of genes that are truly differentially expressed over two sample varieties, after adjusting for hidden subject-specific effects of residual heterogeneity. / GPL-3	noarch
r-svdvisual	1.1	Some visualization tools based on Singular Value Decomposition / GPL-2	noarch
r-svenssonm	0.1.0	Obtain parameters of Svensson's Method, including percentage agreement, systematic change and individual change. Also, the contingency table can be generated. Svensson's Method is a rank-invariant nonparametric method for the analysis of ordered scales which measures the level of change both from systematic and individual aspects. For the details, please refer to Svensson E. Analysis of systematic and random differences between paired ordinal categorical data [dissertation]. Stockholm: Almqvist & Wiksell International; 1993. / GPL-3	noarch
r-svgpanzoom	0.3.3	This 'htmlwidget' provides pan and zoom interactivity to R graphics, including 'base', 'lattice', and 'ggplot2'. The interactivity is provided through the 'svg-pan-zoom.js' library. Various options to the widget can tailor the pan and zoom experience to nearly any user desire. / MIT	noarch
r-svgui	1.0.0	The SciViews svGUI package eases the management of Graphical User Interfaces (GUI) in R. It is independent from any particular GUI widgets (Tk, Gtk2, native, ...). It centralizes info about GUI elements currently used, and it dispatches GUI calls to the particular toolkits in use in function of the context (is R run at the terminal, within a Tk application, a HTML page?). / GPL-2	noarch
r-svmisc	1.1.0	Miscellaneous functions for SciViews or general use: manage a temporary environment attached to the search path for temporary variables you do not want to save() or load(), test if Aqua, Mac, Win, ... Show progress bar, etc. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-svmplus	1.0.1	Implementation of Support Vector Machines Plus (SVM) for classification problems. See (Vladimir et. al, 2009, <doi:10.1016/j.neunet.2009.06.042>) for theoretical details and see (Li et. al, 2016, < https://github.com/okbalefthanded/svmplus_matlab >) for implementation details in ‘MATLAB’. / GPL-3	noarch
r-svn	1.0	Determines networks of significant synchronization between the discrete states of nodes; see Tumminello et al <doi:10.1371/journal.pone.0017994>. / GPL (>= 2.0)	noarch
r-svs	1.1.0	Various tools for semantic vector spaces, such as correspondence analysis (simple, multiple and discriminant), latent semantic analysis, probabilistic latent semantic analysis, non-negative matrix factorization, latent class analysis and EM clustering. Furthermore, there are specialized distance measures, plotting functions and some helper functions. / GPL-3	noarch
r-svsweave	0.9.8	Supporting functions for the GUI API (Sweave functions) / GPL-2	noarch
r-svunit	0.7.1	A complete unit test system and functions to implement its GUI part / GPL-2	noarch
r-swagger	3.9.2	A collection of ‘HTML’, ‘JavaScript’, and ‘CSS’ assets that dynamically generate beautiful documentation from a ‘Swagger’ compliant API: < https://swagger.io/specification/ >. / Apache License 2.0 file LICENSE	noarch
r-swapclass	1.0.1	A null model randomizing semi-quantitative multi-classes (or ordinal) data by swapping sub-matrices while both the row and the column marginal sums are held constant. / GPL-3	noarch
r-swcrtdesign	3.0	A set of tools for examining the design and analysis aspects of stepped wedge cluster randomized trials (SW CRT) based on a repeated cross-sectional sampling scheme (Hussey MA and Hughes JP (2007) Contemporary Clinical Trials 28:182-191. <doi:10.1016/j.cct.2006.05.007>). / GPL-2	noarch
r-swdft	1.0.0	Implements the Sliding Window Discrete Fourier Transform (SWDFT). Also provides statistical methods based on the SWDFT, and graphical tools to display the outputs. / MIT	noarch
r-sweidnumbr	1.4.1	Structural handling of identity numbers used in the Swedish administration such as personal identity numbers (‘personnummer’) and organizational identity numbers (‘organisationsnummer’). / BSD_2_clause	noarch
r-swirl	2.4.4	Use the R console as an interactive learning environment. Users receive immediate feedback as they are guided through self-paced lessons in data science and R programming. / MIT	noarch
r-swissair	1.1.5	Ozone, NOx (= Sum of nitrogen monoxide and nitrogen dioxide), nitrogen monoxide, ambient temperature, dew point, wind speed and wind direction at 3 sites around lake of Lucerne in Central Switzerland in 30 min time resolution for year 2004. / GPL-3	noarch
r-swissmrp	0.62	Provides a number of useful functions to employ MrP for small area prediction in Switzerland. Based on a hierarchical model and survey data one can derive cantonal preference measures. The package allows to automatize the prediction and post-stratification steps. It further provides adequate print, summary, map, and plot functions for objects of its class. / GPL-2	noarch
r-switchr	0.13.5	Provides an abstraction for managing, installing, and switching between sets of installed R packages. This allows users to maintain multiple package libraries simultaneously, e.g. to maintain strict, package-version-specific reproducibility of many analyses, or work within a development/production release paradigm. Introduces a generalized package installation process which supports multiple repository and non-repository sources and tracks package provenance. / Artistic-2.0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-sybil	2.1.5	This Systems Biology Package (Gelius-Dietrich et. al. (2012) <doi:10.1186/1752-0509-7-125>) implements algorithms for constraint based analyses of metabolic networks, e.g. flux-balance analysis (FBA), minimization of metabolic adjustment (MOMA), regulatory on/off minimization (ROOM), robustness analysis and flux variability analysis. The package is easily extendable for additional algorithms. Most of the current LP/MILP solvers are supported via additional packages. / GPL-3	noarch
r-syll	0.1_5	Provides the hyphenation algorithm used for ‘TeX’/‘LaTeX’ and similar software, as proposed by Liang (1983, < https://tug.org/docs/liang/ >). Mainly contains the function hyphen() to be used for hyphenation/syllable counting of text objects. It was originally developed for and part of the ‘koRpus’ package, but later released as a separate package so it’s lighter to have this particular functionality available for other packages. Support for various languages needs be added on-the-fly or by plugin packages (< https://undocumeantit.github.io/repos/ >); this package does not include any language specific data. Due to some restrictions on CRAN, the full package sources are only available from the project homepage. To ask for help, report bugs, request features, or discuss the development of the package, please subscribe to the koRpus-dev mailing list (< http://korporusml.reaktanz.de/ >). / GPL-3	noarch
r-sym.arma	1.0	Functions for fitting the Autoregressive and Moving Average Symmetric Model for univariate time series introduced by Maior and Cysneiros (2018), <doi:10.1007/s00362-016-0753-z>. Fitting method: conditional maximum likelihood estimation. For details see: Wei (2006), Time Series Analysis: Univariate and Multivariate Methods, Section 7.2. / GPL-2	noarch
r-synbreeddata	1.5	Data sets for the ‘synbreed’ package with three data sets from cattle, maize and mice to illustrate the functions in the ‘synbreed’ R package. All data sets are stored in the gpData format introduced in the ‘synbreed’ package. This research was funded by the German Federal Ministry of Education and Research (BMBF) within the AgroClustEr Synbreed - Synergistic plant and animal breeding (FKZ 0315528A). / GPL-2	noarch
r-synchrony	0.3.7	Methods for computing spatial, temporal, and spatiotemporal statistics including: empirical univariate, bivariate and multivariate variograms; fitting variogram models; phase locking and synchrony analysis; generating autocorrelated and cross-correlated matrices. / GPL-2	noarch
r-syncmove	0.1_0	The function ‘syncSubsample’ subsamples temporal data of different entities so that the result only contains synchronal events. The function ‘mci’ calculates the Movement Coordination Index (MCI, see reference on help page for function ‘mci’) of a data set created with the function ‘syncSubsample’. / GPL-2	noarch
r-synet	2.0	Infers sympatry matrices from distributional data and analyzes them in order to identify groups of species cohesively connected. / GPL-3	noarch
r-syntaxr	0.8.0	A set of functions for generating ‘SPSS’ syntax files from the R environment. / MIT	noarch
r-sys	3.2	Drop-in replacements for the base system2() function with fine control and consistent behavior across platforms. Supports clean interruption, timeout, background tasks, and streaming STDIN / STDOUT / STDERR over binary or text connections. Arguments on Windows automatically get encoded and quoted to work on different locales. / MIT file LICENSE	linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-t2eq</code>	1.1	Contains functions for applying the T ² -test for equivalence. The T ² -test for equivalence is a multivariate two-sample equivalence test. Distance measure of the test is the Mahalanobis distance. For multivariate normally distributed data the T ² -test for equivalence is exact and UMPI. The function <code>T2EQ()</code> implements the T ² -test for equivalence according to Wellek (2010) <DOI:10.1201/ebk1439808184>. The function <code>T2EQ.dissolution.profiles.hoffelder()</code> implements a variant of the T ² -test for equivalence according to Hoffelder (2016) < http://www.ecv.de/suse_item.php?suseId=Zlpil8430 > for the equivalence comparison of highly variable dissolution profiles. / GPL-3	noarch
<code>r-tablaxlsx</code>	1.2.2	Some functions are included in this package for writing tables in Excel format suitable for distribution. / GPL-3	noarch
<code>r-table1</code>	1.1	Create HTML tables of descriptive statistics, as one would expect to see as the first table (i.e. Table 1) in a medical/epidemiological journal article. / GPL-3	noarch
<code>r-table1heatmap</code>	1.1	Table 1 is the classical way to describe the patients in a clinical study. The amount of splits in the data in such a table is limited. <code>Table1Heatmap</code> draws a heatmap of all crosstables that can be generated with the data. Users can choose between showing the actual crosstables or direction of effect of associations, and highlight associations by number of patients or p-values. / LGPL-3	noarch
<code>r-tablehtml</code>	2.0.0	A tool to create and style HTML tables with CSS. These can be exported and used in any application that accepts HTML (e.g. ‘shiny’, ‘rmarkdown’, ‘PowerPoint’). It also provides functions to create CSS files (which also work with shiny). / MIT	noarch
<code>r-tablematrix</code>	0.82.0	Provides two classes extending ‘data.table’ class. Simple ‘tableList’ class wraps ‘data.table’ and any additional structures together. More complex ‘tableMatrix’ class combines ‘data.table’ and ‘matrix’. See < http://github.com/InferenceTechnologies/tableMatrix > for more information and examples. / GPL-2	noarch
<code>r-tablemonster</code>	1.7	Provides a user friendly interface to generation of booktab style tables using ‘xtable’. / GPL-2	noarch
<code>r-tableplot</code>	0.3.5	Description: / GPL-3	noarch
<code>r-tablerdash</code>	0.1.0	‘R’ interface to the ‘Tabler’ HTML template. See more here < https://tabler.io >. ‘tablerDash’ is a light ‘Bootstrap 4’ dashboard template. There are different layouts available such as a one page dashboard or a multi page template, where the navigation menu is contained in the navigation bar. A fancy example is available at < https://dgranjon.shinyapps.io/shinyMons/ >. / GPL-2	noarch
<code>r-tabletolongform</code>	1.3.2	A wrapper to a set of algorithms designed to recognise positional cues present in hierarchical for-human Tables (which would normally be interpreted visually by the human brain) to decompose, then reconstruct the data into machine-readable LongForm Dataframes. / GPL-3	noarch
<code>r-tabulizerjars</code>	1.0.1	‘Java’ .jar files for the ‘Tabula’ < http://tabula.technology/ > ‘Java’ library, which are required by the ‘tabulizer’ R package. The version numbering of this package corresponds to versions of ‘tabula-java’ library releases < https://github.com/tabulapdf/tabula-java/releases/ >. / MIT	noarch
<code>r-tabulog</code>	0.1.1	Convert semi-structured log files (such as ‘Apache’ access.log files) into a tabular format (data.frame) using a standard template system. / MIT	noarch
<code>r-tabusearch</code>	1.1.1	Tabu search algorithm for binary configurations. A basic version of the algorithm as described by Fouskakis and Draper (2007) <doi:10.1111/j.1751-5823.2002.tb00174.x>. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tactile	0.2.0	Extensions to ‘lattice’, providing new high-level functions, methods for existing functions, panel functions, and a theme. / GPL-3	noarch
r-tailloss	1.0	Set of tools to estimate the probability in the upper tail of the aggregate loss distribution using different methods: Panjer recursion, Monte Carlo simulations, Markov bound, Cantelli bound, Moment bound, and Chernoff bound. / GPL-2 GPL-3	noarch
r-taipan	0.1.2	A tool to help create shiny apps for selecting and annotating elements of images. Users must supply images, questions, and answer choices. The user interface is a dynamic shiny app, that displays the images and questions and answer choices. The data generated can be saved to a file that can be used for subsequent analysis. The original purpose was to annotate still images from tennis video for face recognition and emotion detection purposes. / GPL-3	noarch
r-tandem	1.0.2	A two-stage regression method that can be used when various input data types are correlated, for example gene expression and methylation in drug response prediction. In the first stage it uses the upstream features (such as methylation) to predict the response variable (such as drug response), and in the second stage it uses the downstream features (such as gene expression) to predict the residuals of the first stage. In our manuscript (Aben et al., 2016, <doi:10.1093/bioinformatics/btw449>), we show that using TANDEM prevents the model from being dominated by gene expression and that the features selected by TANDEM are more interpretable. / GPL-2	noarch
r-tangram	0.4	Provides an extensible formula system to quickly and easily create production quality tables. The steps of the process are formula parser, statistical content generation from data, to rendering. Each step of the process is separate and user definable thus creating a set of building blocks for highly extensible table generation. A user is not limited by any of the choices of the package creator other than the formula grammar. For example, one could chose to add a different S3 rendering function and output a format not provided in the default package. Or possibly one would rather have Gini coefficients for their statistical content. Routines to achieve New England Journal of Medicine style, Lancet style and Hmisc::summaryM() statistics are provided. The package contains rendering for HTML5, Rmarkdown and an indexing format for use in tracing and tracking are provided. / GPL-3	noarch
r-taoteprogramming	1.0	Art-like behavior based on randomness / Unlimited	noarch
r-tapkee	1.0	Wrapper for using ‘tapkee’ command line utility, it allows to run it from inside R and catch the results for further analysis and plotting. ‘Tapkee’ is a program for fast dimension reduction (see < http://tapkee.lisitsyn.me/ > for more details). / GPL-2	noarch
r-tar	1.0	Identification and estimation of the autoregressive threshold models with Gaussian noise, as well as positive-valued time series. The package provides the identification of the number of regimes, the thresholds and the autoregressive orders, as well as the estimation of remain parameters. The package implements the methodology from the 2005 paper: Modeling Bivariate Threshold Autoregressive Processes in the Presence of Missing Data <DOI:10.1081/STA-200054435>. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tariff	1.0.5	Implement the Tariff algorithm for coding cause-of-death from verbal autopsies. The Tariff method was originally proposed in James et al (2011) <DOI:10.1186/1478-7954-9-31> and later refined as Tariff 2.0 in Serina, et al. (2015) <DOI:10.1186/s12916-015-0527-9>. Note that this package was not developed by authors affiliated with the Institute for Health Metrics and Evaluation and thus unintentional discrepancies may exist between the this implementation and the implementation available from IHME. / GPL-2	noarch
r-tariffx	1.0.6	A collection of various utility and convenience functions. / GPL-2	noarch
r-tatest	1.0	The ta-test is a modified two-sample or two-group t-test of Gosset (1908). In small samples with less than 15 replicates, the ta-test significantly reduces type I error rate but has almost the same power with the t-test and hence can greatly enhance reliability or reproducibility of discoveries in biology and medicine. The ta-test can test single null hypothesis or multiple null hypotheses without needing to correct p-values. / GPL-3	noarch
r-tatoo	1.1.1	Functions to combine data.frames in ways that require additional effort in base R, and to add metadata (id, title, ...) that can be used for printing and xlsx export. The 'Tatoo_report' class is provided as a convenient helper to write several such tables to a workbook, one table per worksheet. Tatoo is built on top of 'openxlsx', but intimate knowledge of that package is not required to use tatoo. / MIT	noarch
r-taup.r	1.5	Evaluates traveltimes and ray paths using predefined Earth (or other planet) models. Includes phase plotting routines. The IASP91 (Kennett and Engdahl, 1991 <doi:10.1111/j.1365-246X.1991.tb06724.x>) and AK135 (Kennett et al., 1995 <doi:10.1111/j.1365-246X.1995.tb03540.x>) Earth models are included, and most important arrival phases can be evaluated. / GPL-3	noarch
r-taxicabca	0.1.0	Computation and visualization of Taxicab Correspondence Analysis, Choulakian (2006) <doi:10.1007/s11336-004-1231-4>. Classical correspondence analysis (CA) is a statistical method to analyse 2-dimensional tables of positive numbers and is typically applied to contingency tables (Benzecri, J.-P. (1973). L'Analyse des Donnees. Volume II. L'Analyse des Correspondances. Paris, France: Dunod). Classical CA is based on the Euclidean distance. Taxicab CA is like classical CA but is based on the Taxicab or Manhattan distance. For some tables, Taxicab CA gives more informative results than classical CA. / GPL-2	noarch
r-tbd	0.1.0	Estimation of the survivor average causal effect under outcomes truncated by death, which requires the existence of a substitution variable. It can be applied to both experimental and observational data. / GPL-2	noarch
r-tbdiag	0.1	This package provides functions to assist researchers working in the field of tuberculosis diagnostics. Functions for the interpretation of two popular interferon-gamma release assays are provided, and additional functionality is planned. / MIT	noarch
r-tcgaretriever	1.3	The Cancer Genome Atlas (TCGA) is a program aimed at improving our understanding of Cancer Biology. Several TCGA Datasets are available online. 'TCGAretriever' helps accessing and downloading TCGA data hosted on 'cBioPortal' via its Web Interface (see < http://www.cbioportal.org/web_api.jsp > for more information). Features of 'TCGAretriever' include: 1) it is very simple to use (get all the TCGA data you need with a few lines of code); 2) performance (smooth and reliable data download via 'http'); 3) it is tailored for downloading large volumes of data. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tciapathfinder	1.0.5	A wrapper for The Cancer Imaging Archive’s REST API. The Cancer Imaging Archive (TCIA) hosts de-identified medical images of cancer available for public download, as well as rich metadata for each image series. TCIA provides a REST API for programmatic access to the data. This package provides simple functions to access each API endpoint. For more information, see < https://github.com/pamelarussell/TCIApathfinder > and TCIA’s website. / MIT	noarch
r-tcltk2	1.2.1	A series of additional Tcl commands and Tk widgets with style and various functions (under Windows: DDE exchange, access to the registry and icon manipulation) to supplement the tcltk package / LGPL-3	noarch
r-tdamapper	1.0	Topological Data Analysis using Mapper (discrete Morse theory). Generate a 1-dimensional simplicial complex from a filter function defined on the data: 1. Define a filter function (lens) on the data. 2. Perform clustering within within each level set and generate one node (vertex) for each cluster. 3. For each pair of clusters in adjacent level sets with a nonempty intersection, generate one edge between vertices. The function mapper1D uses a filter function with codomain R, while the the function mapper2D uses a filter function with codomain R^2 . / GPL-3	noarch
r-tdcor	0.1.2	The Time-Delay Correlation algorithm (TDCor) reconstructs the topology of a gene regulatory network (GRN) from time-series transcriptomic data. The algorithm is described in details in Lavenus et al., Plant Cell, 2015. It was initially developed to infer the topology of the GRN controlling lateral root formation in Arabidopsis thaliana. The time-series transcriptomic dataset which was used in this study is included in the package to illustrate how to use it. / GPL-2	noarch
r-tdpanalysis	0.99	Set of functions designed to help in the analysis of TDP sensors. Features includes dates and time conversion, weather data interpolation, daily maximum of tension analysis and calculations required to convert sap flow density data to sap flow rates at the tree and plot scale (For more information see : Granier (1985) <DOI:10.1051/forest:19850204> & Granier (1987) <DOI:10.1093/treephys/3.4.309>). / GPL-2	noarch
r-tdroc	1.0	Compute time-dependent ROC curve from censored survival data using non-parametric weight adjustments. / GPL-2	noarch
r-tdsc	1.0.0	Functions for performing time domain signal coding as used in Chesmore (2001) <doi:10.1016/S0003-682X(01)00009-3>, and related tasks. This package creates the standard S-matrix and A-matrix (with variable lag), has tools to convert coding matrices into distributed matrices, provides published code-books and allows for extraction of code sequences. / GPL-3	noarch
r-teachingdemos	2.10	Demonstration functions that can be used in a classroom to demonstrate statistical concepts, or on your own to better understand the concepts or the programming. / Artistic-2.0	noarch
r-teachingsampling	3.4.2	Allows the user to draw probabilistic samples and make inferences from a finite population based on several sampling designs. / GPL-2	noarch
r-teachnet	0.7.1	Can fit neural networks with up to two hidden layer and two different error functions. Also able to handle a weight decay. But just able to compute one output neuron and very slow. / GPL-2	noarch
r-teamr	0.0.1	Package of wrapper functions using R6 class to send requests to Microsoft ‘Teams’ < https://products.office.com/en-us/microsoft-teams/group-chat-software > through webhooks. When you need to share information or data from R to ‘Teams’, rather than copying/pasting, you can use this package to send well-formatted output from multiple R objects. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-teda	0.1.1	The typicality and eccentricity data analysis (TEDA) framework was put forward by Angelov (2013) <DOI:10.14313/JAMRIS_2-2014/16>. It has been further developed into multiple different techniques since, and provides a non-parametric way of determining how similar an observation, from a process that is not purely random, is to other observations generated by the process. This package provides code to use the batch and recursive TEDA methods that have been published. / GPL-3	noarch
r-teereg	1.1	For fitting multiple linear regressions, the ordinary least squares approach is sensitive to outliers and/or violations of model assumptions. The trimmed elemental estimators are more robust to such situations. This package contains functions for computing the trimmed elemental estimates, as well as for creating the bias-corrected and accelerated bootstrap confidence intervals based on elemental regressions. / GPL-2	noarch
r-tejapi	1.0.1	Functions for interacting directly with the Taiwan Economic Journal API to offer data in R. For more information go to < https://api.tej.com.tw >. / MIT	noarch
r-telegram	0.6.0	R wrapper around the Telegram Bot API (http://core.telegram.org/bots/api) to access Telegram's messaging facilities with ease (e.g. you send messages, images, files from R to your smartphone). / GPL-3	noarch
r-telegram.bot	2.3.1	Provides a pure interface for the 'Telegram Bot API' < http://core.telegram.org/bots/api >. In addition to the pure API implementation, it features a number of tools to make the development of 'Telegram' bots with R easy and straightforward, providing an easy-to-use interface that takes some work off the programmer. / GPL-3	noarch
r-tempcont	0.1.0	Method to estimate the effect of the trend in predictor variables on the observed trend of the response variable using mixed models with temporal autocorrelation. See Fernández-Martínez et al. (2017 and 2019) <doi:10.1038/s41598-017-08755-8> <doi:10.1038/s41558-018-0367-7>. / GPL-2	noarch
r-tempcyclesdata	1.0.1	This is the data companion package to the package tempcycles. This package includes the metadata, linear, and cycling parameters from Recent geographic convergence in diurnal and annual temperature cycling flattens global thermal profiles, Wang & Dillon, Nature Climate Change, 4, 988-992 (2014). doi:10.1038/nclimate2378. / GPL-2	noarch
r-tempdisagg	0.25.0	Temporal disaggregation methods are used to disaggregate and interpolate a low frequency time series to a higher frequency series, where either the sum, the average, the first or the last value of the resulting high frequency series is consistent with the low frequency series. Temporal disaggregation can be performed with or without one or more high frequency indicator series. Contains the methods of Chow-Lin, Santos-Silva-Cardoso, Fernandez, Litterman, Denton and Denton-Cholette. / GPL-3	noarch
r-tempor	1.0.4	TEMPO (TEmporal Modeling of Pathway Outliers) is a pathway-based outlier detection approach for finding pathways showing significant changes in temporal expression patterns across conditions. Given a gene expression data set where each sample is characterized by an age or time point as well as a phenotype (e.g. control or disease), and a collection of gene sets or pathways, TEMPO ranks each pathway by a score that characterizes how well a partial least squares regression (PLSR) model can predict age as a function of gene expression in the controls and how poorly that same model performs in the disease. TEMPO v1.0.3 is described in Pietras (2018) <doi:10.1145/3233547.3233559>. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-temptr</code>	0.9.9	Analysis and visualization of data from temporal sensory methods, including for temporal check-all-that-apply (TCATA) and temporal dominance of sensations (TDS). / GPL-2	noarch
<code>r-tenispolar</code>	0.1.4	Implementation of ZENIT-POLAR substitution cipher method of encryption using by default the TENIS-POLAR cipher. This last cipher of encryption became famous through the collection of Brazilian books Os Karas by the author Pedro Bandeira. For more details, see A Cryptographic Dictionary (GC&CS, 1944). / GPL-3	noarch
<code>r-tensor</code>	1.5	The tensor product of two arrays is notionally an outer product of the arrays collapsed in specific extents by summing along the appropriate diagonals. / GPL-2	noarch
<code>r-tensorflow</code>	1.13	Interface to ‘TensorFlow’ < https://www.tensorflow.org/ >, an open source software library for numerical computation using data flow graphs. Nodes in the graph represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) communicated between them. The flexible architecture allows you to deploy computation to one or more ‘CPUs’ or ‘GPUs’ in a desktop, server, or mobile device with a single ‘API’. ‘TensorFlow’ was originally developed by researchers and engineers working on the Google Brain Team within Google’s Machine Intelligence research organization for the purposes of conducting machine learning and deep neural networks research, but the system is general enough to be applicable in a wide variety of other domains as well. / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-tensorr</code>	0.1.1	Provides methods to manipulate and store sparse tensors. Tensors are multidimensional generalizations of matrices (two dimensional) and vectors (one dimensional). / GPL-3	noarch
<code>r-tenstr</code>	1.0.1	A collection of functions for Kronecker structured covariance estimation and testing under the array normal model. For estimation, maximum likelihood and Bayesian equivariant estimation procedures are implemented. For testing, a likelihood ratio testing procedure is available. This package also contains additional functions for manipulating and decomposing tensor data sets. This work was partially supported by NSF grant DMS-1505136. Details of the methods are described in Gerard and Hoff (2015) < doi:10.1016/j.jmva.2015.01.020 > and Gerard and Hoff (2016) < doi:10.1016/j.laa.2016.04.033 >. / GPL-3	noarch
<code>r-teqr</code>	6.0_0	The TEQR package contains software to calculate the operating characteristics for the TEQR and the ACT designs. The TEQR (toxicity equivalence range) design is a toxicity based cumulative cohort design with added safety rules. The ACT (Activity constrained for toxicity) design is also a cumulative cohort design with additional safety rules. The unique feature of this design is that dose is escalated based on lack of activity rather than on lack of toxicity and is de-escalated only if an unacceptable level of toxicity is experienced. / GPL-2	noarch
<code>r-terapplusb</code>	1.0	This package is for the comparison of various types of AB escalation rules for dose finding trials. / LGPL-2.1	noarch
<code>r-ternary</code>	1.1.1	Plots ternary diagrams using the standard graphics functions. An alternative to ‘ggtern’, which uses the ‘ggplot2’ family of plotting functions. / GPL-2	noarch
<code>r-ternvis</code>	1.2	A suite of functions for visualising ternary probabilistic forecasts, as discussed in the paper by Jupp (2012) < doi:10.1098/rsta.2011.0350 >. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-testassay	0.1.0	A common way of validating a biological assay for is through a procedure, where m levels of an analyte are measured with n replicates at each level, and if all m estimates of the coefficient of variation (CV) are less than some pre-specified level, then the assay is declared validated for precision within the range of the m analyte levels. Two limitations of this procedure are: there is no clear statistical statement of precision upon passing, and it is unclear how to modify the procedure for assays with constant standard deviation. We provide tools to convert such a procedure into a set of m hypothesis tests. This reframing motivates the $m:n:q$ procedure, which upon completion delivers a 100q% upper confidence limit on the CV. Additionally, for a post-validation assay output of y , the method gives an “effective standard deviation interval” of $\log(y)$ plus or minus r , which is a 68% confidence interval on $\log(\mu)$, where μ is the expected value of the assay output for that sample. Further, the $m:n:q$ procedure can be straightforwardly applied to constant standard deviation assays. We illustrate these tools by applying them to a growth inhibition assay. / MIT	noarch
r-testdriver	0.5.1	Provides data sets for teaching statistics and data science courses. It includes a sample of data from John Edmund Kerrich’s famous coinflip experiment. These are data that I use for teaching SOC 4015 / SOC 5050 at Saint Louis University (SLU). The package also contains an R Markdown template with the required formatting for assignments in my courses SOC 4015, SOC 4650, SOC 5050, and SOC 5650 at SLU. / GPL-3	noarch
r-testequavar	0.1.2	Tests the hypothesis that variances are homogeneous or not using bootstrap. The procedure uses a variance-based statistic, and is derived from a normal-theory test. The test equivalently expressed the hypothesis as a function of the log contrasts of the population variances. A box-type acceptance region is constructed to test the hypothesis. See Cahoy (2010) <doi:10.1016/j.csda.2010.04.012>. / GPL-3	noarch
r-tester	0.1.7	tester allows you to test characteristics of common R objects. / GPL-3	noarch
r-testfunctions	0.2.0	Test functions are often used to test computer code. They are used in optimization to test algorithms and in metamodeling to evaluate model predictions. This package provides test functions that can be used for any purpose. Some functions are taken from < https://www.sfu.ca/~ssurjano >, but their R code is not used. / GPL-3	noarch
r-testingsimilarity	1.1	Provides a bootstrap test which decides whether two dose response curves can be assumed as equal concerning their maximum absolute deviation. A plenty of choices for the model types are available, which can be found in the ‘DoseFinding’ package, which is used for the fitting of the models. See <doi:10.1080/01621459.2017.1281813> for details. / GPL-3	noarch
r-testit	0.9	Provides two convenience functions <code>assert()</code> and <code>test_pkg()</code> to facilitate testing R packages. / GPL	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-testscorer	1.7.2	GUI for entering test items and obtaining raw and transformed scores. The results are shown on the console and can be saved to a tabular text file for further statistical analysis. The user can define his own tests and scoring procedures through a GUI. / GPL-2	noarch
r-testthat	2.1.1	Software testing is important, but, in part because it is frustrating and boring, many of us avoid it. ‘testthat’ is a testing framework for R that is easy learn and use, and integrates with your existing ‘workflow’. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-texreg	1.36.2	Converts coefficients, standard errors, significance stars, and goodness-of-fit statistics of statistical models into LaTeX tables or HTML tables/MS Word documents or to nicely formatted screen output for the R console for easy model comparison. A list of several models can be combined in a single table. The output is highly customizable. New model types can be easily implemented. / GPL-2 GPL-3	noarch
r-textgrid	1.0.1	The software application Praat can be used to annotate waveform data (e.g., to mark intervals of interest or to label events). (See http://www.fon.hum.uva.nl/praat/ for more information about Praat.) These annotations are stored in a Praat TextGrid object, which consists of a number of interval tiers and point tiers. An interval tier consists of sequential (i.e., not overlapping) labeled intervals. A point tier consists of labeled events that have no duration. The ‘textgRid’ package provides S4 classes, generics, and methods for accessing information that is stored in Praat TextGrid objects. / GPL-3	noarch
r-textile	0.1.2	Contains real images of the same textile material with/without local defects, which were used in Bui and Apley (2017) <doi:10.1080/00401706.2017.1302362>. / GPL-2	noarch
r-textometry	0.1.4	Statistical exploration of textual corpora using several methods from French ‘Textometrie’ (new name of ‘Lexicometrie’) and French ‘Data Analysis’ schools. It includes methods for exploring irregularity of distribution of lexicon features across text sets or parts of texts (Specificity analysis); multi-dimensional exploration (Factorial analysis), etc. Those methods are used in the TXM software. / GPL-3	noarch
r-textrank	0.3.0	The ‘textrank’ algorithm is an extension of the ‘Pagerank’ algorithm for text. The algorithm allows to summarize text by calculating how sentences are related to one another. This is done by looking at overlapping terminology used in sentences in order to set up links between sentences. The resulting sentence network is next plugged into the ‘Pagerank’ algorithm which identifies the most important sentences in your text and ranks them. In a similar way ‘textrank’ can also be used to extract keywords. A word network is constructed by looking if words are following one another. On top of that network the ‘Pagerank’ algorithm is applied to extract relevant words after which relevant words which are following one another are combined to get keywords. More information can be found in the paper from Mihalcea, Rada & Tarau, Paul (2004) < http://www.aclweb.org/anthology/W04-3252 >. / MPL-2.0	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-textreg	0.1.5	Function for sparse regression on raw text, regressing a labeling vector onto a feature space consisting of all possible phrases. / MIT	linux-64, osx-64, win-64
r-textshape	1.6.0	Tools that can be used to reshape and restructure text data. / GPL-2	noarch
r-texttinyr	1.1.3	It offers functions for splitting, parsing, tokenizing and creating a vocabulary for big text data files. Moreover, it includes functions for building a document-term matrix and extracting information from those (term-associations, most frequent terms). It also embodies functions for calculating token statistics (collocations, look-up tables, string dissimilarities) and functions to work with sparse matrices. Lastly, it includes functions for Word Vector Representations (i.e. ‘GloVe’, ‘fasttext’) and incorporates functions for the calculation of (pairwise) text document dissimilarities. The source code is based on ‘C11’ and exported in R through the ‘Rcpp’, ‘RcppArmadillo’ and ‘BH’ packages. / GPL-3	linux-64, osx-64, win-64
r-textutils	0.1_1	Utilities for handling character vectors that store human-readable text (either plain or with markup, such as HTML or LaTeX). The package provides, in particular, functions that help with the preparation of plain-text reports (e.g. for expanding and aligning strings that form the lines of such reports); the package also provides generic functions for transforming R objects to HTML and to plain text. / GPL-3	noarch
r-tfcox	0.1.0	In Cox’s proportional hazard model, covariates are modeled as linear function and may not be flexible. This package implements additive trend filtering Cox proportional hazards model as proposed in Jiacheng Wu & Daniela Witten (2019) Flexible and Interpretable Models for Survival Data, Journal of Computational and Graphical Statistics, <DOI:10.1080/10618600.2019.1592758>. The fitted functions are piecewise polynomial with adaptively chosen knots. / GPL-2	linux-64, osx-64, win-64
r-tfdatasets	1.13.1	Interface to ‘TensorFlow’ Datasets, a high-level library for building complex input pipelines from simple, re-usable pieces. See < https://www.tensorflow.org/programmers_guide/datasets > for additional details. / Apache License 2.0	noarch
r-tfer	1.1	Statistical interpretation of forensic glass transfer (Simulation of the probability distribution of recovered glass fragments). / GPL-2	noarch
r-tfmpvalue	0.0.8	In putative Transcription Factor Binding Sites (TFBSs) identification from sequence/alignments, we are interested in the significance of certain match score. TFMPvalue provides the accurate calculation of P-value with score threshold for Position Weight Matrices, or the score with given P-value. It is an interface to code originally made available by Helene Touzet and Jean-Stephane Varre, 2007, Algorithms Mol Biol:2, 15. Touzet and Varre (2007) <DOI:10.1186/1748-7188-2-15>. / GPL-2	linux-64, osx-64, win-64
r-tframe	2015.12.1	A kernel of functions for programming time series methods in a way that is relatively independently of the representation of time. Also provides plotting, time windowing, and some other utility functions which are specifically intended for time series. See the Guide distributed as a vignette, or ?tframe.Intro for more details. (User utilities are in package tfplot.) / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-tfruns</code>	1.4	Create and manage unique directories for each ‘TensorFlow’ training run. Provides a unique, time stamped directory for each run along with functions to retrieve the directory of the latest run or latest several runs. / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-tfse</code>	0.5.0	A collection of useful tools for programming and writing-scripts. Several functions are simple wrappers around base R functions that extend their functionality while also providing some convenient properties—regular expression functions that automatically detect look-ahead and look-behind statements, a read-line function that suppresses incomplete-final-line warnings and automatically opens and closes connections, a version of substrings that starts from the end of strings, etc. Other functions are useful for checking whether packages are installed, omitting missing data, and showing in-use connections. / MIT	noarch
<code>r-tfx</code>	0.1.0	Connects R to TrueFX(tm) for free streaming real-time and historical tick-by-tick market data for dealable interbank foreign exchange rates with millisecond detail. / GPL-3	noarch
<code>r-tgcd</code>	2.1	Deconvolving thermoluminescence glow curves according to various kinetic models (first-order, second-order, general-order, and mixed-order) using a modified Levenberg-Marquardt algorithm. It provides the possibility of setting constraints or fixing any of parameters. It offers an interactive way to initialize parameters by clicking with a mouse on a plot at positions where peak maxima should be located. The optimal estimate is obtained by trial-and-error. It also provides routines for simulating first-order, second-order, and general-order glow peaks. / GPL-2 GPL-3	linux-64, osx-64, win-64
<code>r-tggd</code>	0.1.1	Density, distribution function, quantile function and random generation for the Truncated Generalised Gamma Distribution (also in log10(x) and ln(x) space). / GPL-3	noarch
<code>r-tgram</code>	0.2_3	Functions to compute and plot tracheidograms, as in De Soto et al. (2011) <doi:10.1139/x11-045>. / GPL-2	noarch
<code>r-th.data</code>	1.0_1	Contains data sets used in other packages Torsten Hothorn maintains. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r-thankr</code>	1.0.0	Find out who maintains the packages you use in your current session or in your package library and maybe say ‘thank you’. / MIT	noarch
<code>r-thankyoustars</code>	0.2.0	A tool for starring GitHub repositories. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-thermindex	0.2.0	Calculates several thermal comfort indexes using temperature, wind speed and relative humidity values, calculating indexes such as Humidex, windchill, Discomfort Index and others. / GPL-2	noarch
r-thermocouple	1.0.2	Temperature measurement data, equations and methods for thermocouples, wire RTD, thermistors, IC thermometers, bimetallic strips and the ITS-90. / GPL-3	noarch
r-thgenetics	0.4.2	A step-up test for genetic rare variants in a gene or in a pathway. The method determines an optimal grouping of rare variants analytically. The method has been described in Hoffmann TJ, Marini NJ, and Witte JS (2010) <doi:10.1371/journal.pone.0013584>. / GPL-3	linux-64, osx-64, win-64
r-thinknum	1.3.0	This package interacts directly with the Thinknum API to offer data in a number of formats usable in R / GPL-2	noarch
r-threearmedtrials	1.0.3	Design and analyze three-arm non-inferiority or superiority trials which follow a gold-standard design, i.e. trials with an experimental treatment, an active, and a placebo control. Method for the following distributions are implemented: Poisson (Mielke and Munk (2009) <arXiv:0912.4169>), negative binomial (Muetze et al. (2016) <doi:10.1002/sim.6738>), normal (Pigeot et al. (2003) <doi:10.1002/sim.1450>; Hasler et al. (2009) <doi:10.1002/sim.3052>), binary (Friede and Kieser (2007) <doi:10.1002/sim.2543>), nonparametric (Muetze et al. (2017) <doi:10.1002/sim.7176>), exponential (Mielke and Munk (2009) <arXiv:0912.4169>). / GPL-2	linux-64, osx-64, win-64
r-threeboost	1.1	This package implements a thresholded version of the EEBoost algorithm described in [Wolfson (2011, JASA)]. EEBoost is a general-purpose method for variable selection which can be applied whenever inference would be based on an estimating equation. The package currently implements variable selection based on the Generalized Estimating Equations, but can also accommodate user-provided estimating functions. Thresholded EEBoost is a generalization which allows multiple variables to enter the model at each boosting step. / GPL-3	noarch
r-threegroups	0.21	Implements the Maximum Likelihood estimator for baseline, placebo, and treatment groups (three-group) experiments with non-compliance proposed by Gerber, Green, Kaplan, and Kern (2010). / GPL-2	noarch
r-threejs	0.3.1	Create interactive 3D scatter plots, network plots, and globes using the ‘three.js’ visualization library (< https://threejs.org >). / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-threeway	1.1.3	Component analysis for three-way data arrays by means of Candecomp/Parafac, Tucker3, Tucker2 and Tucker1 models. / GPL-2	noarch
r-threewords	0.1.0	A connector to the ‘What3Words’ (http://what3words.com/) service, which represents each 3m by 3m square on earth with a unique trio of English-language words. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-threg	1.0.3	Fit a threshold regression model based on the first-hitting-time of a boundary by the sample path of a Wiener diffusion process. The threshold regression methodology is well suited to applications involving survival and time-to-event data. / GPL-2	noarch
r-thregi	1.0.4	Fit a threshold regression model for Interval Censored Data based on the first-hitting-time of a boundary by the sample path of a Wiener diffusion process. The threshold regression methodology is well suited to applications involving survival and time-to-event data. / GPL-2	noarch
r-thresholdroc	2.7	Functions that provide point and interval estimations of optimum thresholds for continuous diagnostic tests. The methodology used is based on minimizing an overall cost function in the two- and three-state settings. The package also provides functions for sample size determination and estimation of diagnostic accuracy measures. It also includes graphical tools. / GPL-2	noarch
r-thsls	0.1	Fit the Simultaneous Systems of Linear Equations using Three-stage Least Squares. / GPL-3	noarch
r-tibble	2.1.1	Provides a 'tbl_df' class (the 'tibble') that provides stricter checking and better formatting than the traditional data frame. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-tibbrconnector	1.5.1	Post messages to tibbr from within R. / BSD_3_clause	noarch
r-tickexec	1.1	Functions to execute orders in backtesting using tick data. A testing platform was established by the four major execution functions, namely 'LimitBuy', 'LimitSell', 'MarketBuy' and 'MarketSell', which enclosed all tedious aspects (such as queueing for order executions and calculate actual executed volumes) for order execution using tick data. Such that one can focus on the logic of strategies, rather than its execution. / GPL-3	noarch
r-tictoc	1.0	This package provides the timing functions 'tic' and 'toc' that can be nested. One can record all timings while a complex script is running, and examine the values later. It is also possible to instrument the timing calls with custom callbacks. In addition, this package provides class 'Stack', implemented as a vector, and class 'List', implemented as a list, both of which support operations 'push', 'pop', 'first', 'last' and 'clear'. / Apache License (== 2.0) file LICENSE	noarch
r-tiddlywikir	1.0.1	Utilities to generate wiki reports in TiddlyWiki format. / GPL-2	noarch
r-tideharmonics	0.1_1	Implements harmonic analysis of tidal and sea-level data. Over 400 harmonic tidal constituents can be estimated, all with daily nodal corrections. Time-varying mean sea-levels can also be used. / BSD_3_clause	noarch
r-tides	2.1	Calculate Characteristics of Quasi-Periodic Time Series, e.g. Estuarine Water Levels. / GPL-3	noarch
r-tidetables	0.0.2	Tide analysis and prediction of predominantly semi-diurnal tides with two high waters and two low waters during one lunar day (~24.842 hours, ~1.035 days). The analysis should preferably cover an observation period of at least 19 years. For shorter periods, for example, the nodal cycle can not be taken into account, which particularly affects the height calculation. The main objective of this package is to produce tide tables. / GPL-3	noarch

Continued on next page

Name	Version	Summary/License	Platform
r-tidyr	0.8.3	An evolution of 'reshape2'. It's designed specifically for data tidying (not general reshaping or aggregating) and works well with 'dplyr' data pipelines. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-tidysselect	0.2.5	A backend for the selecting functions of the 'tidyverse'. It makes it easy to implement select-like functions in your own packages in a way that is consistent with other 'tidyverse' interfaces for selection. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-tidytext	0.2.0	Text mining for word processing and sentiment analysis using 'dplyr', 'ggplot2', and other tidy tools. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-tidyverse	1.2.1	The 'tidyverse' is a set of packages that work in harmony because they share common data representations and 'API' design. This package is designed to make it easy to install and load multiple 'tidyverse' packages in a single step. Learn more about the 'tidyverse' at < https://tidyverse.org >. / GPL-3 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-tiff	0.1.5	This package provides an easy and simple way to read, write and display bitmap images stored in the TIFF format. It can read and write both files and in-memory raw vectors. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-tightclust	1.1	The functions needed to perform tight clustering Algorithm. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tilegramsr	0.2.0	R spatial objects for Tilegrams. Tilegrams are tiled maps where the region size is proportional to the certain characteristics of the dataset. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-tilting	1.1.1	Implements an algorithm for variable selection in high-dimensional linear regression using the tilted correlation, a new way of measuring the contribution of each variable to the response which takes into account high correlations among the variables in a data-driven way. / GPL-2	noarch
r-timechange	0.0.1	Efficient routines for manipulation of date-time objects while accounting for time-zones and daylight saving times. The package includes utilities for updating of date-time components (year, month, day etc.), modification of time-zones, rounding of date-times, period addition and subtraction etc. Parts of the ‘CCTZ’ source code, released under the Apache 2.0 License, are included in this package. See < https://github.com/google/cctz > for more details. / GPL-3	linux-64, osx-64, win-64
r-timedate	3043.102	The ‘timeDate’ class fulfils the conventions of the ISO 8601 standard as well as of the ANSI C and POSIX standards. Beyond these standards it provides the Financial Center concept which allows to handle data records collected in different time zones and mix them up to have always the proper time stamps with respect to your personal financial center, or alternatively to the GMT reference time. It can thus also handle time stamps from historical data records from the same time zone, even if the financial centers changed day light saving times at different calendar dates. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-timedelay	1.0.8	We provide a toolbox to estimate the time delay between the brightness time series of gravitationally lensed quasar images via Bayesian and profile likelihood approaches. The model is based on a state-space representation for irregularly observed time series data generated from a latent continuous-time Ornstein-Uhlenbeck process. Our Bayesian method adopts scientifically motivated hyper-prior distributions and a Metropolis-Hastings within Gibbs sampler, producing posterior samples of the model parameters that include the time delay. A profile likelihood of the time delay is a simple approximation to the marginal posterior distribution of the time delay. Both Bayesian and profile likelihood approaches complement each other, producing almost identical results; the Bayesian way is more principled but the profile likelihood is easier to implement. / GPL-2	noarch
r-timeordered	0.9.9	Approaches for incorporating time into network analysis. Methods include: construction of time-ordered networks (temporal graphs); shortest-time and shortest-path-length analyses; resource spread calculations; data resampling and rarefaction for null model construction; reduction to time-aggregated networks with variable window sizes; application of common descriptive statistics to these networks; vector clock latencies; and plotting functionalities. The package supports <doi:10.1371/journal.pone.0020298>. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-timeprojection	0.2.0	Extract useful time components of a date object, such as day of week, week-end, holiday, day of month, etc, and put it in a data frame. This can be used to create many predictor variables out of a single time variable, which can then be used in a regression or decision tree. Also includes function plotCalendarHeatmap which draws a calendar and overlays a heatmap based on values. / GPL-3	noarch
r-timer	1.1.0	Provides a 'timeR' class that makes timing codes easier. One can create 'timeR' objects and use them to record all timings, and extract recordings as data frame for later use. / Apache License (== 2.0) file LICENSE	noarch
r-timereg	1.9.4	Programs for Martinussen and Scheike (2006), 'Dynamic Regression Models for Survival Data', Springer Verlag. Plus more recent developments. Additive survival model, semiparametric proportional odds model, fast cumulative residuals, excess risk models and more. Flexible competing risks regression including GOF-tests. Two-stage frailty modelling. PLS for the additive risk model. Lasso in the 'ahaz' package. / GPL-2	linux-64, osx-64, win-64
r-timesboot	1.0	Computes bootstrap CI for the sample ACF and periodogram / GPL-2	noarch
r-timeseries	3042.002	Provides a class and various tools for financial time series. This includes basic functions such as scaling and sorting, subsetting, mathematical operations and statistical functions. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-timetools	1.14	Objects to manipulate sequential and seasonal time series. Sequential time series based on time instants and time durations are handled. Both can be regularly or unevenly spaced (overlapping durations are allowed). Only POSIX* format are used for dates and times. The following classes are provided : 'POSIXcti', 'POSIXctp', 'TimeIntervalDataFrame', 'TimeInstantDataFrame', 'SubtimeDataFrame' ; methods to switch from a class to another and to modify the time support of series (hourly time series to daily time series for instance) are also defined. Tools provided can be used for instance to handle environmental monitoring data (not always produced on a regular time base). / GPL-3	linux-64, osx-64, win-64
r-timevis	0.5	Create rich and fully interactive timeline visualizations. Timelines can be included in Shiny apps and R markdown documents, or viewed from the R console and 'RStudio' Viewer. 'timevis' includes an extensive API to manipulate a timeline after creation, and supports getting data out of the visualization into R. Based on the 'vis.js' Timeline module and the 'htmlwidgets' R package. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-timevtree	0.3.1	Estimates time varying regression effects under Cox type models in survival data using classification and regression tree. The codes in this package were originally written in S-Plus for the paper Survival Analysis with Time-Varying Regression Effects Using a Tree-Based Approach, by Xu, R. and Adak, S. (2002) <doi:10.1111/j.0006-341X.2002.00305.x>, Biometrics, 58: 305-315. Development of this package was supported by NIH grants AG053983 and AG057707, and by the UCSD Altman Translational Research Institute, NIH grant UL1TR001442. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. The example data are from the Honolulu Heart Program/Honolulu Asia Aging Study (HHP/HAAS). / GPL-2	noarch
r-timewarp	1.0.15	Date sequence, relative date calculations, and date manipulation with business days and holidays. Works with Date and POSIXt classes. / GPL-3	noarch
r-timsac	1.3.6	Functions for statistical analysis, prediction and control of time series based mainly on Akaike and Nakagawa (1988) <ISBN 978-90-277-2786-2>. / GPL-2	linux-64, osx-64, win-64
r-tinflex	1.5	A universal non-uniform random number generator for quite arbitrary distributions with piecewise twice differentiable densities. / GPL-2	linux-64, osx-64, win-64
r-tinsel	0.0.1	Instead of nesting function calls, annotate and transform functions using #. comments. / MIT	noarch
r-tint	0.1.2	A ‘tufte’-alike style for ‘rmarkdown’. A modern take on the ‘Tufte’ design for pdf and html vignettes, building on the ‘tufte’ package with additional contributions from the ‘knitr’ and ‘ggtufte’ package, and also acknowledging the key influence of ‘envisioned css’. / GPL-3	noarch
r-tinyproject	0.6.1	Creates useful files and folders for data analysis projects and provides functions to manage data, scripts and output files. Also provides a project template for ‘Rstudio’. / GPL-2	noarch
r-tinytest	1.0.0	Provides a lightweight (zero-dependency) and easy to use unit testing framework. Main features: install tests with the package. Test results are treated as data that can be stored and manipulated. Test files are R scripts interspersed with test commands, that can be programmed over. Fully automated build-install-test sequence for packages. Skip tests when not run locally (e.g. on CRAN). Flexible and configurable output printing. Compare computed output with output stored with the package. Run tests in parallel. Extensible by other packages. Report side effects. / GPL-3	noarch
r-tinytex	0.12	Helper functions to install and maintain the ‘LaTeX’ distribution named ‘TinyTeX’ (< https://yihui.name/tinytex/ >), a lightweight, cross-platform, portable, and easy-to-maintain version of ‘TeX Live’. This package also contains helper functions to compile ‘LaTeX’ documents, and install missing ‘LaTeX’ packages automatically. / MIT file LICENSE	linux-64, noarch, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tiobeindexr	0.1.1	Get latest ‘TIOBE’ Programming Index Tables. The ‘TIOBE’ Programming Community index is an indicator of the popularity of programming languages from < https://www.tiobe.com/tiobe-index/ >. / AGPL-3	noarch
r-tipom	1.0.2	TIPOM is based on a methodology that was developed in the 1960s by Bernardino Bagolini. The basic idea is to use the three simple dimensions of length, width and thickness of each lithic artefact to classify them in discrete groups and infer their function. / GPL-3	noarch
r-tippy	0.0.1	‘Htmlwidget’ of ‘Tippyjs’ to add tooltips to ‘Shiny’ apps and ‘R markdown’ documents. / MIT	noarch
r-tis	1.37	IFunctions and S3 classes for time indexes and time indexed series, which are compatible with FAME frequencies. / Unlimited	linux-64, osx-64, win-64
r-titan	1.0_1	GUI to analyze mass spectrometric data on the relative abundance of two substances from a titration series. / GPL-2	noarch
r-titanic	0.1.0	This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner Titanic, summarized according to economic status (class), sex, age and survival. Whereas the base R Titanic data found by calling data(Titanic) is an array resulting from cross-tabulating 2201 observations, these data sets are the individual non-aggregated observations and formatted in a machine learning context with a training sample, a testing sample, and two additional data sets that can be used for deeper machine learning analysis. These data sets are also the data sets downloaded from the Kaggle competition and thus lowers the barrier to entry for users new to R or machine learning. / CC0	noarch
r-titrationcurves	0.1.0	A collection of functions to plot acid/base titration curves (pH vs. volume of titrant), complexation titration curves (pMetal vs. volume of EDTA), redox titration curves (potential vs. volume of titrant), and precipitation titration curves (either pAnalyte or pTitrant vs. volume of titrant). Options include the titration of mixtures, the ability to overlay two or more titration curves, and the ability to show equivalence points. / GPL-2	noarch
r-tkrgl	0.8	Provides ‘TK’ widget tools for the ‘rgl’ package. / GPL	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r- tkrplot	0.0_24	Simple mechanism for placing R graphics in a Tk widget / GPL	linux-32, linux-64, osx-64, win-32, win-64
r- tkrplotr	0.1.1	Display a plot in a Tk canvas. / GPL-2	noarch
r- tlemix	0.1.3	TLE implements a general framework for robust fitting of finite mixture models. Parameter estimation is performed using the EM algorithm. / GPL-3	noarch
r- tlim	0.1.5	Computation of effects under linear, logistic and Poisson regression models with transformed variables. Logarithm and power transformations are allowed. Effects can be displayed both numerically and graphically in both the original and the transformed space of the variables. / GPL-2	noarch
r- tlmec	0.0_2	Fit a linear mixed effects model for censored data with Student-t or normal distributions. The errors are assumed independent and identically distributed. / GPL (>= 3.0)	noarch
r- tls	0.1.0	Functions for point and interval estimation in error-in-variables models via total least squares or generalized total least squares method. See Golub and Van Loan (1980) <doi:10.1137/0717073>, Gleser (1981) < https://www.jstor.org/stable/2240867 >, Ivan Markovsky and Huffel (2007) <doi:10.1016/j.sigpro.2007.04.004> for more information. / GPL-3	noarch
r- tm	0.7_6	A framework for text mining applications within R. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r- tm.plugin.alceste	1.1	This package provides a tm Source to create corpora from a corpus prepared in the format used by the Alceste application (i.e. a single text file with inline meta-data). It is able to import both text contents and meta-data (starred) variables. / GPL-2	noarch
r- tm.plugin.dc	0.2_8	A plug-in for the text mining framework tm to support text mining in a distributed way. The package provides a convenient interface for handling distributed corpus objects based on distributed list objects. / GPL-2	noarch
r- tm.plugin.europresse	1.4	Provides a ‘tm’ Source to create corpora from articles exported from the ‘Europresse’ content provider as HTML files. It is able to read both text content and meta-data information (including source, date, title, author and pages). / GPL-2	noarch
r- tm.plugin.factiva	1.7	Provides a ‘tm’ Source to create corpora from articles exported from the Dow Jones ‘Factiva’ content provider as XML or HTML files. It is able to read both text content and meta-data information (including source, date, title, author, subject, geographical coverage, company, industry, and various provider-specific fields). / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-tm.plugin.lexisnexis</code>	1.4.0	Provides a 'tm' Source to create corpora from articles exported from the 'LexisNexis' content provider as HTML files. It is able to read both text content and meta-data information (including source, date, title, author and pages). Note that the file format is highly unstable: there is no warranty that this package will work for your corpus, and you may have to adjust the code to adapt it to your particular format. / GPL-2	noarch
<code>r-tm.plugin.mail</code>	0.2.1	A plug-in for the tm text mining framework providing mail handling functionality. / GPL-3	noarch
<code>r-tm.plugin.webmining</code>	1.3	Facilitate text retrieval from feed formats like XML (RSS, ATOM) and JSON. Also direct retrieval from HTML is supported. As most (news) feeds only incorporate small fractions of the original text tm.plugin.webmining even retrieves and extracts the text of the original text source. / GPL-3	noarch
<code>r-tmlr</code>	1.1.2	Useful functions to connect to 'TM1' < https://www.ibm.com/uk-en/marketplace/planning-and-analytics > instance from R via REST API. With the functions in the package, data can be imported from 'TM1' via mdx view or native view, data can be sent to 'TM1', processes and chores can be executed, and cube and dimension metadata information can be taken. / GPL-2	noarch
<code>r-tmb</code>	1.7.15	With this tool, a user should be able to quickly implement complex random effect models through simple C templates. The package combines 'CppAD' (C automatic differentiation), 'Eigen' (templated matrix-vector library) and 'CHOLMOD' (sparse matrix routines available from R) to obtain an efficient implementation of the applied Laplace approximation with exact derivatives. Key features are: Automatic sparseness detection, parallelism through 'BLAS' and parallel user templates. / GPL-2	linux-64, osx-64, win-64
<code>r-tmcalculator</code>	1.0.0	The melting temperature of nucleic acid sequences can be calculated in three method, the Wallace rule (Thein & Wallace (1986) <doi:10.1016/S0140-6736(86)90739-7>), empirical formulas based on G and C content (Marmur J. (1962) <doi:10.1016/S0022-2836(62)80066-7>, Schildkraut C. (2010) <doi:10.1002/bip.360030207>, Wetmur J G (1991) <10.3109/10409239109114069>, Untergasser,A. (2012) <doi:10.1093/nar/gks596>, von Ahsen N (2001) <PMID:11673362>) and nearest neighbor thermodynamics (Breslauer K J (1986) <doi:10.1073/pnas.83.11.3746>, Sugimoto N (1996) <doi:10.1093/nar/24.22.4501>, Allawi H (1998) <doi:10.1093/nar/26.11.2694>, SantaLucia J (2004) <doi:10.1146/annurev.biophys.32.110601.141800>, Freier S (1986) <doi:10.1073/pnas.83.24.9373>, Xia T (1998) <doi:10.1021/bi9809425>, Chen JL (2012) <doi:10.1021/bi3002709>, Bommarito S (2000) <doi:10.1093/nar/28.9.1929>, Turner D H (2010) <doi:10.1093/nar/gkp892>, Sugimoto N (1995) <doi:10.1016/S0048-9697(98)00088-6>, Allawi H T (1997) <doi:10.1021/bi962590c>, Santalucia N (2005) <doi:10.1093/nar/gki918>), and it can also be corrected with salt ions and chemical compound (SantaLucia J (1996) <doi:10.1021/bi951907q>, SantaLucia J(1998) <doi:10.1073/pnas.95.4.1460>, Owczarzy R (2004) <doi:10.1021/bi034621r>, Owczarzy R (2008) <doi:10.1021/bi702363u>). / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tmcn	0.2.13	A Text mining toolkit for Chinese, which includes facilities for Chinese string processing, Chinese NLP supporting, encoding detecting and converting. Moreover, it provides some functions to support ‘tm’ package in Chinese. / LGPL-3	linux-64, osx-64, win-64
r-tmdb	1.0	Provides an R-interface to the TMDb API (see TMDb API on ">http://docs.themoviedb.apiary.io/#>). The Movie Database (TMDb) is a popular user editable database for movies and TV shows (see https://www.themoviedb.org/). / Artistic-2.0	noarch
r-tmg	0.3	Random number generation of truncated multivariate Gaussian distributions using Hamiltonian Monte Carlo. The truncation is defined using linear and/or quadratic polynomials. / GPL-2	linux-64, osx-64, win-64
r-tmpm	1.0.3	Trauma Mortality prediction for ICD-9, ICD-10, and AIS lexicons in long or wide format based on Dr. Alan Cook’s tmpm mortality model. / GPL-2	noarch
r-tmvmixnorm	1.0.2	Efficient sampling of truncated multivariate (scale) mixtures of normals under linear inequality constraints is nontrivial due to the analytically intractable normalizing constant. Meanwhile, traditional methods may subject to numerical issues, especially when the dimension is high and dependence is strong. Algorithms proposed by Li and Ghosh (2015) <doi: 10.1080/15598608.2014.996690> are adopted for overcoming difficulties in simulating truncated distributions. Efficient rejection sampling for simulating truncated univariate normal distribution is included in the package, which shows superiority in terms of acceptance rate and numerical stability compared to existing methods and R packages. An efficient function for sampling from truncated multivariate normal distribution subject to convex polytope restriction regions based on Gibbs sampler for conditional truncated univariate distribution is provided. By extending the sampling method, a function for sampling truncated multivariate Student’s t distribution is also developed. Moreover, the proposed method and computation remain valid for high dimensional and strong dependence scenarios. Empirical results in Li and Ghosh (2015) <doi: 10.1080/15598608.2014.996690> illustrated the superior performance in terms of various criteria (e.g. mixing and integrated auto-correlation time). / GPL-2	noarch
r-tmvnsim	1.0.2	Importance sampling from the truncated multivariate normal using the GHK (Geweke-Hajivassiliou-Keane) simulator. Unlike Gibbs sampling which can get stuck in one truncation sub-region depending on initial values, this package allows truncation based on disjoint regions that are created by truncation of absolute values. The GHK algorithm uses simple Cholesky transformation followed by recursive simulation of univariate truncated normals hence there are also no convergence issues. Importance sample is returned along with sampling weights, based on which, one can calculate integrals over truncated regions for multivariate normals. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tnc	0.1.0	Node centrality measures for temporal networks. Available measures are temporal degree centrality, temporal closeness centrality and temporal betweenness centrality defined by Kim and Anderson (2012) <doi:10.1103/PhysRevE.85.026107>. Applying the REN algorithm by Hanke and Foraita (2017) <doi:10.1186/s12859-017-1677-x> when calculating the centrality measures keeps the computational running time linear in the number of graph snapshots. Further, all methods can run in parallel up to the number of nodes in the network. / GPL-3	noarch
r-tnet	3.0.14	R package for analyzing weighted, two-mode, and longitudinal networks. / GPL-3	noarch
r-todor	0.0.5	This is a simple addin to 'RStudio' that finds all 'TODO', 'FIX ME', 'CHANGED' etc. comments in your project and shows them as a markers list. / MIT	noarch
r-tokenbrowser	0.1.0	Create browsers for reading full texts from a token list format. Information obtained from text analyses (e.g., topic modeling, word scaling) can be used to annotate the texts. / GPL-3	linux-64, osx-64, win-64
r-tokenizers	0.2.1	Convert natural language text into tokens. Includes tokenizers for shingled n-grams, skip n-grams, words, word stems, sentences, paragraphs, characters, shingled characters, lines, tweets, Penn Treebank, regular expressions, as well as functions for counting characters, words, and sentences, and a function for splitting longer texts into separate documents, each with the same number of words. The tokenizers have a consistent interface, and the package is built on the 'stringi' and 'Rcpp' packages for fast yet correct tokenization in 'UTF-8'. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-tokenizers.bpe	0.1.0	Unsupervised text tokenizer focused on computational efficiency. Wraps the 'YouTokenToMe' library < https://github.com/VKCOM/YouTokenToMe > which is an implementation of fast Byte Pair Encoding (BPE) < https://www.aclweb.org/anthology/P16-1162 >. / MPL-2.0	linux-64, osx-64, win-64
r-toordinal	1.1.0	Language specific cardinal to ordinal number conversion. / GPL-3	noarch
r-topicmodels	0.2.9	Provides an interface to the C code for Latent Dirichlet Allocation (LDA) models and Correlated Topics Models (CTM) by David M. Blei and co-authors and the C code for fitting LDA models using Gibbs sampling by Xuan-Hieu Phan and co-authors. / GPL-2	linux-64, osx-64, win-64
r-topmodel	0.7.3	Set of hydrological functions including an R implementation of the hydrological model TOPMODEL, which is based on the 1995 FORTRAN version by Keith Beven. From version 0.7.0, the package is put into maintenance mode. / GPL-2	linux-64, osx-64, win-64
r-topsis	1.0	Evaluation of alternatives based on multiple criteria using TOPSIS method. / GPL-2	noarch
r-tosls	1.0	Fit an Instrumental Variables Two Stage Least Squares model / Artistic-2.0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-totalcensus	0.6.1	Download summary files from Census Bureau < https://www2.census.gov/ > and extract data, in particular high resolution data at block, block group, and tract level, from decennial census and American Community Survey 1-year and 5-year estimates. / MIT	noarch
r-totalcopheneticindex	1.0.1	For a given phylogenetic tree, calculates the Total Cophenetic Index. Reference: A. Mir, F. Rossello, L. A. Rotger (2013). A new balance index for phylogenetic trees. Math. Biosci. 241, 125-136 <doi:10.1016/j.mbs.2012.10.005>. / Unlimited	noarch
r-touch	0.1_4	R implementation of the software tools developed in the H-CUP (Healthcare Cost and Utilization Project) < https://www.hcup-us.ahrq.gov > and AHRQ (Agency for Healthcare Research and Quality) < https://www.ahrq.gov >. It currently contains functions for mapping ICD-9 codes to the AHRQ comorbidity measures and translating ICD-9 (resp. ICD-10) codes to ICD-10 (resp. ICD-9) codes based on GEM (General Equivalence Mappings) from CMS (Centers for Medicare and Medicaid Services). / GPL-3	linux-64, osx-64, win-64
r-tourr	0.5.6	Implements geodesic interpolation and basis generation functions that allow you to create new tour methods from R. / MIT	noarch
r-toxtestd	2.0	Calculates sample size and dose allocation for binary toxicity tests, using the Fish Embryo Toxicity Test as example. An optimal test design is obtained by running (i) spoD (calculate the number of individuals to test under control conditions), (ii) setD (estimate the minimal sample size per treatment given the users precision requirements) and (iii) doseD (construct an individual dose scheme). / GPL-2	noarch
r-tp.idm	1.5	Estimation of transition probabilities for the illness-death model. Both the Aalen-Johansen estimator for a Markov model and a novel non-Markovian estimator by de Una-Alvarez and Meira-Machado (2015) <doi:10.1111/biom.12288>, see also Balboa and de Una-Alvarez (2018) <doi:10.18637/jss.v083.i10>, are included. / GPL-2	linux-64, osx-64, win-64
r-tpauc	2.1.1	Tools for estimating and inferring two-way partial area under receiver operating characteristic curves (two-way pAUC), partial area under receiver operating characteristic curves (pAUC), and partial area under ordinal dominance curves (pODC). Methods includes Mann-Whitney statistic and Jackknife, etc. / GPL-2	noarch
r-tpe	1.0.1	This package implements the greedy approximation for tree preserving embedding. / MIT	noarch
r-tpes	1.0.0	A bioinformatics tool for the estimation of the tumor purity from sequencing data. It uses the set of putative clonal somatic single nucleotide variants within copy number neutral segments to call tumor cellularity. / MIT	noarch
r-tpmsm	1.2.2	Estimation of transition probabilities for the illness-death model and or the three-state progressive model. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tracerer	2.0.1	'BEAST2' (< http://www.beast2.org >) is a widely used Bayesian phylogenetic tool, that uses DNA/RNA/protein data and many model priors to create a posterior of jointly estimated phylogenies and parameters. 'Tracer' (< http://tree.bio.ed.ac.uk/software/tracer/ >) is a GUI tool to parse and analyze the files generated by 'BEAST2'. This package provides a way to parse and analyze 'BEAST2' input files without active user input, but using R function calls instead. / GPL-3	linux-64, osx-64, win-64
r-track	1.1.9	Automatically stores objects in files on disk so that files are rewritten when objects are changed, and so that objects are accessible but do not occupy memory until they are accessed. Keeps track of times when objects are created and modified, and caches some basic characteristics of objects to allow for fast summaries of objects. Also provides a command history mechanism that saves the last command to a history file after each command completes. / GPL-3	noarch
r-trading	1.2	Contains trades from the five major assets classes and also functionality to use pricing curves, rating tables, CSAs and add-on tables. The implementation follows an object oriented logic whereby each trade inherits from more abstract classes while also the curves/tables are objects. There is a lot of functionality focusing on the counterparty credit risk calculations however the package can be used for trading applications in general. / GPL-3	noarch
r-trampr	1.0.8	Matching terminal restriction fragment length polymorphism ('TRFLP') profiles between unknown samples and a database of known samples. TRAMPR facilitates analysis of many unknown profiles at once, and provides tools for working directly with electrophoresis output through to generating summaries suitable for community analyses with R's rich set of statistical functions. TRAMPR also resolves the issues of multiple 'TRFLP' profiles within a species, and shared 'TRFLP' profiles across species. / GPL-2	noarch
r-transcriber	0.0.0	Transcribes audio to text with the HP IDOL API. Includes functions to upload files, retrieve transcriptions, and monitor jobs. / GPL-3	noarch
r-translation.ko	0.0.1	R2version 2.1.0 and later support Korean translations of program messages. The continuous efforts have been made by < http://developer.r-project.org/TranslationTeams.html > The R Documentation files are licensed under the General Public License, version 2 or 3. This means that the pilot project to translate them into Korean has permission to reproduce them and translate them. This work is done with GNU 'gettext' utilities. The portable object template is updated a weekly basis or whenever changes are necessary. Comments and corrections via email to the maintainer is of course most welcome. In order to voluntarily participate in or offer your help with this translation, please contact the maintainer. To check the change and progress of Korean translation, please visit < http://www.openstatistics.net >. / GPL-2	noarch
r-transmodel	2.1	A unified estimation procedure for the analysis of right censored data using linear transformation models. / GPL-2	noarch
r-transp	0.1	Implementation of two transportation problem algorithms. 1. North West Corner Method 2. Minimum Cost Method or Least cost method. For more technical details about the algorithms please refer below URLs. < http://www.universalteacherpublications.com/univ/ebooks/or/Ch5/nw.htm >. < http://personal.maths.surrey.ac.uk/st/J.F/chapter7.pdf >. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-transport	0.12_0	Solve optimal transport problems. Compute Wasserstein distances (a.k.a. Kantorovitch, Fortet–Mourier, Mallows, Earth Mover’s, or minimal L _p distances), return the corresponding transference plans, and display them graphically. Objects that can be compared include grey-scale images, (weighted) point patterns, and mass vectors. / GPL-2	linux-64, osx-64, win-64
r-transurv	1.2.0	A structural transformation model for a latent, quasi-independent truncation time as a function of the observed dependent truncation time and the event time, and an unknown dependence parameter. The dependence parameter is chosen to minimize the conditional Kendall’s tau (Martin and Betensky, 2005) <doi:10.1198/016214504000001538>. The marginal distribution for the truncation time and the event time are completely left unspecified. / GPL-3	linux-64, osx-64, win-64
r-trapezoid	2.0_0	The trapezoid package provides dtrapezoid, ptrapezoid, qtrapezoid, and rtrapezoid functions for the trapezoidal distribution. / GPL-3	linux-64, osx-64, win-64
r-tree	1.0_4	Classification and regression trees. / GPL-2 GPL-3	linux-64, osx-64, win-64
r-treebase	0.1.4	Interface to the API for ‘TreeBASE’ < http://treebase.org > from ‘R.’ ‘TreeBASE’ is a repository of user-submitted phylogenetic trees (of species, population, or genes) and the data used to create them. / CC0	noarch
r-treeclust	1.1_7	Create a measure of inter-point dissimilarity useful for clustering mixed data, and, optionally, perform the clustering. / GPL-2	noarch
r-treecm	1.2.2	The centre of mass is a crucial data for arborists in order to consolidate a tree using steel or dynamic cables. Given field-recorded data on branchiness of a tree, the package: (i) computes and plots the centre of mass of the tree itself, (ii) computes branches slenderness coefficient in order to aid the arborist identify potentially dangerous branches, and (iii) computes the force acting on a ground plinth and its best position relating to the tree centre of mass, should the tree need to be stabilized by a steel cable. / GPL-2	noarch
r-treelet	1.1	Treelets provides a novel construction of multi-scale bases that extends wavelets to non-smooth signals. It returns a multi-scale orthonormal basis, where the final computed basis functions are supported on nested clusters in a hierarchical tree. Both the tree and the basis, which are constructed simultaneously, reflect the internal structure of the data. / GPL-2	noarch
r-treeman	1.1.3	S4 class and methods for intuitive and efficient phylogenetic tree manipulation. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-treeperm	1.6	An implementation of permutation tests in R, supporting both exact and asymptotic K sample test of data locations. The p value of exact tests is found using tree algorithms. Tree algorithms treat permutations of input data as tree nodes and perform constraint depth-first searches for permutations that fall into the critical region of a test systematically. Pruning of tree search and optimisations at C level enable exact tests for certain large data sets. / GPL-2	linux-64, osx-64, win-64
r-trekfont	0.9.3	Provides a collection of true type and open type Star Trek-themed fonts. / GPL-3	noarch
r-trendchange	0.1.0	Innovative Trend Analysis is a graphical method to examine the trends in time series data. Sequential Mann-Kendall test uses the intersection of prograde and retrograde series to indicate the possible change point in time series data. Distribution free cumulative sum charts indicate location and significance of the change point in time series. Zekai, S. (2011). <doi:10.1061/(ASCE)HE.1943-5584.0000556>. Grayson, R. B. et al. (1996). Hydrological Recipes: Estimation Techniques in Australian Hydrology. Cooperative Research Centre for Catchment Hydrology, Australia, p. 125. Sneyers, S. (1990). On the statistical analysis of series of observations. Technical note no 5 143, WMO No 725 415. Secretariat of the World Meteorological Organization, Geneva, 192 pp. / GPL-3	noarch
r-trendsegmentr	1.0.0	Performs the detection of point anomalies and linear trend changes for univariate time series by implementing the bottom-up unbalanced wavelet transformation proposed by H. Maeng and P. Fryzlewicz (2019) < http://personal.lse.ac.uk/maengh/ >. The estimated number and locations of the change-points are returned with the piecewise-linear estimator for signal. / GPL-3	noarch
r-trialsize	1.3	functions and examples in Sample Size Calculation in Clinical Research. / GPL (>= 2.15.1)	linux-64, osx-64, win-64
r-triangle	0.12	Provides the r, q, p, and d distribution functions for the triangle distribution. / GPL-2	noarch
r-triangulation	0.5.0	Measuring angles between points in a landscape is much easier than measuring distances. When the location of three points is known the position of the observer can be determined based solely on the angles between these points as seen by the observer. This task (known as triangulation) however requires onerous calculations - these calculations are automated by this package. / LGPL-3	noarch
r-triebeard	0.3.0	‘Radix trees’, or ‘tries’, are key-value data structures optimised for efficient lookups, similar in purpose to hash tables. ‘triebeard’ provides an implementation of ‘radix trees’ for use in R programming and in developing packages with ‘Rcpp’. / MIT	linux-64, osx-64, win-64
r-trimcluster	0.1_2	Trimmed k-means clustering. / GPL-3	noarch
r-trimr	1.0.1	Provides various commonly-used response time trimming methods, including the recursive / moving-criterion methods reported by Van Selst and Jolicoeur (1994). By passing trimming functions raw data files, the package will return trimmed data ready for inferential testing. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-triosgl	1.1.0	Fit a trio model via penalized maximum likelihood. The model is fit for a path of values of the penalty parameter. This package is based on Noah Simon, et al. (2011) <doi:10.1080/10618600.2012.681250>. / GPL-3	linux-64, osx-64, win-64
r-tripack	1.3_8	A constrained two-dimensional Delaunay triangulation package providing both triangulation and generation of voronoi mosaics of irregular spaced data. / ACM file LICENSE (Restricts use)	linux-64, osx-64, win-64
r-tripsanddipr	0.1.0	Uses read counts for biallelic single nucleotide polymorphisms (SNPs) to compare the likelihoods for the observed read counts given that a sample is either diploid or triploid. It allows parameters to be specified to account for sequencing error rates and allelic bias. For details of the algorithm, please see Delomas (2019) <doi:10.1111/1755-0998.13073>. / MIT	noarch
r-tropalgebra	0.1.1	It includes functions like tropical addition, tropical multiplication for vectors and matrices. In tropical algebra, the tropical sum of two numbers is their minimum and the tropical product of two numbers is their ordinary sum. For more information see also I. Simon (1988) Recognizable sets with multiplicities in the tropical semi ring: Volume 324 Lecture Notes I Computer Science, pages 107-120 <doi: 10.1007/BFb0017135>. / GPL-3	noarch
r-tropicalsparse	0.1.0	Some of the basic tropical algebra functionality is provided for sparse matrices by applying sparse matrix storage techniques. Some of these are addition and multiplication of vectors and matrices, dot product of the vectors in tropical form and some general equations are also solved using tropical algebra. / GPL-3	noarch
r-trotter	0.6	Class definitions and constructors for pseudo-vectors containing all permutations, combinations and subsets of objects taken from a vector. Simplifies working with structures commonly encountered in combinatorics. / GPL-3	noarch
r-trueskill	0.1	An implementation of the TrueSkill algorithm (Herbrich, R., Minka, T. and Grapel, T) in R; a Bayesian skill rating system with inference by approximate message passing on a factor graph. Used by Xbox to rank gamers and identify appropriate matches. http://research.microsoft.com/en-us/projects/trueskill/default.aspx Current version allows for one player per team. Will update as time permits. Requires R version 3.0 as it is written with Reference Classes. URL: https://github.com/bhoung/trueskill-in-r Acknowledgements to Doug Zongker and Heungsub Lee for their python implementations of the algorithm and for the liberal reuse of Doug's code comments (@dougz and @sublee on github). / GPL-3	noarch
r-truncgof	0.6_0	Goodness-of-fit tests and some adjusted exploratory tools allowing for left truncated data / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-truncnorm	1.0_8	Density, probability, quantile and random number generation functions for the truncated normal distribution. / GPL-2	linux-64, osx-64, win-64
r-truncreg	0.2_5	Estimation of models for truncated Gaussian variables by maximum likelihood. / GPL-2	noarch
r-trust	0.1_7	Does local optimization using two derivatives and trust regions. Guaranteed to converge to local minimum of objective function. / MIT	noarch
r-trustedtimestamping	0.2.6	Trusted Timestamps (tts) are created by incorporating a hash of a file or dataset into a transaction on the decentralized blockchain (Stellar network). The package makes use of a free service provided by < https://stellarapi.io >. / AGPL-3	noarch
r-trustoptim	0.8.6.2	Trust region algorithm for nonlinear optimization. Efficient when the Hessian of the objective function is sparse (i.e., relatively few nonzero cross-partial derivatives). See Braun, M. (2014) <doi:10.18637/jss.v060.i04>. / MPL (>= 2.0)	linux-64, osx-64, win-64
r-trycatchlog	1.1.4	Advanced tryCatch() and try() functions for better error handling (logging, stack trace with source code references and support for post-mortem analysis via dump files). / GPL-3	noarch
r-tsallisqexp	0.9_3	Tsallis distribution also known as the q-exponential family distribution. Provide distribution d, p, q, r functions, fitting and testing functions. Project initiated by Paul Higbie and based on Cosma Shalizi's code. / GPL-2	noarch
r-tsbox	0.2.0	Time series toolkit with identical behavior for all time series classes: 'ts', 'xts', 'data.frame', 'data.table', 'tibble', 'zoo', 'timeSeries', 'tsibble', 'tis' or 'irts'. Also converts reliably between these classes. / GPL-3	noarch
r-tsc	1.0_3	Performs the two-sample comparisons using the following exact test procedures: the exact likelihood-ratio test (LRT) for equality of two normal populations proposed in Zhang et al. (2012); the combined test based on the LRT and Shapiro-Wilk test for normality via the Bonferroni correction technique; the newly proposed density-based empirical likelihood (DBEL) ratio test. To calculate p-values of the DBEL procedures, three procedures are used: (a) the traditional Monte Carlo (MC) method implemented in C, (b) a new interpolation method based on regression techniques to operate with tabulated critical values of the test statistic; (c) a Bayesian type method that uses the tabulated critical values as the prior information and MC generated DBEL-test-statistic's values as data. / GPL-2	linux-64, osx-64, win-64
r-tsdata	2016.8.11	Illustrates the various 'TSdbi' packages with a vignette using time series data from several sources. The vignette also illustrates some simple time series manipulation and plotting using packages 'tframe' and 'tfplot'. / GPL-2	noarch
r-tsdecomp	0.2	ARIMA-model-based decomposition of quarterly and monthly time series data. The methodology is developed and described, among others, in Burman (1980) <DOI:10.2307/2982132> and Hillmer and Tiao (1982) <DOI:10.2307/2287770>. / GPL-2	noarch
r-tsdf	1.1_7	Calculate optimal Zhong's two-/three-stage Phase II designs (see Zhong (2012) <doi:10.1016/j.cct.2012.07.006>). Generate Target Toxicity decision table for Phase I dose-finding (two-/three-stage). This package also allows users to run dose-finding simulations based on customized decision table. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tsdfgs	1.0	Determining training set for genomic selection using a genetic algorithm (Holland J.H. (1975) <DOI:10.1145/1216504.1216510>) or simple exchange algorithm (change an individual every iteration). Three different criteria are used in both algorithms, which are r-score (Ou J.H., Liao C.T. (2018) <DOI:10.6342/NTU201802290>), PEV-score (Akdemir D. et al. (2015) <DOI:10.1186/s12711-015-0116-6>) and CD-score (Laloe D. (1993) <DOI:10.1186/1297-9686-25-6-557>). Phenotypic data for candidate set is not necessary for all these methods. By using it, one may readily determine a training set that can be expected to provide a better training set comparing to random sampling. / GPL-3	linux-64, osx-64, win-64
r-tsdisagg2	0.1.0	Disaggregates low frequency time series data to higher frequency series. Implements the following methods for temporal disaggregation: Boot, Feibes and Lisman (1967) <DOI:10.2307/2985238>, Chow and Lin (1971) <DOI:10.2307/1928739>, Fernandez (1981) <DOI:10.2307/1924371> and Litterman (1983) <DOI:10.2307/1391858>. / GPL-2	noarch
r-tse	0.1.0	Calculates total survey error (TSE) for one or more surveys, using common scale-dependent and/or scale-independent metrics. On TSE, see: Weisberg, Herbert (2005, ISBN:0-226-89128-3); Biemer, Paul (2010) <doi:10.1093/poq/nfq058>. / GPL-2	noarch
r-tseind	0.1.0	Calculates total survey error (TSE) for one or more surveys, using both scale-dependent and scale-independent metrics. Package works directly from the data set, with no hand calculations required: just upload a properly structured data set (see TESTIND and its documentation), properly input column names (see functions documentation), and run your functions. For more on TSE, see: Weisberg, Herbert (2005, ISBN:0-226-89128-3); Biemer, Paul (2010) <doi:10.1093/poq/nfq058>; Biemer, Paul et.al. (2017, ISBN:9781119041672); etc. / GPL-2	noarch
r-tsentropies	0.9	Computes various entropies of given time series. This is the initial version that includes ApEn() and SampEn() functions for calculating approximate entropy and sample entropy. Approximate entropy was proposed by S.M. Pincus in Approximate entropy as a measure of system complexity, Proceedings of the National Academy of Sciences of the United States of America, 88, 2297-2301 (March 1991). Sample entropy was proposed by J. S. Richman and J. R. Moorman in Physiological time-series analysis using approximate entropy and sample entropy, American Journal of Physiology, Heart and Circulatory Physiology, 278, 2039-2049 (June 2000). This package also contains FastApEn() and FastSampEn() functions for calculating fast approximate entropy and fast sample entropy. These are newly designed very fast algorithms, resulting from the modification of the original algorithms. The calculated values of these entropies are not the same as the original ones, but the entropy trend of the analyzed time series determines equally reliably. Their main advantage is their speed, which is up to a thousand times higher. A scientific article describing their properties has been submitted to The Journal of Supercomputing and in present time it is waiting for the acceptance. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tseries	0.10_46	Time series analysis and computational finance. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-tserieschaos	0.1_13	Routines for the analysis of nonlinear time series. This work is largely inspired by the TISEAN project, by Rainer Hegger, Holger Kantz and Thomas Schreiber: < http://www.mpipks-dresden.mpg.de/~tisean/ >. / GPL-2	linux-64, osx-64, win-64
r-tseriesmma	0.1.1	Multiscale multifractal analysis (MMA) (Gierałtowski et al., 2012)<DOI:10.1103/PhysRevE.85.021915> is a time series analysis method, designed to describe scaling properties of fluctuations within the signal analyzed. The main result of this procedure is the so called Hurst surface $h(q,s)$, which is a dependence of the local Hurst exponent h (fluctuation scaling exponent) on the multifractal parameter q and the scale of observation s (data window width). / GPL-2	noarch
r-tsetools	0.1.3	Tools for downloading and organizing data from Tehran Stock Exchange (TSE) < http://new.tse.ir/en/ >. It also performs some descriptive data analysis for assets. / BSD_2_clause	noarch
r-tsewgt	0.1.0	Calculates total survey error (TSE) for a survey under multiple, different weighting schemes, using both scale-dependent and scale-independent metrics. Package works directly from the data set, with no hand calculations required: just upload a properly structured data set (see TESTWGT and its documentation), properly input column names (see functions documentation), and run your functions. For more on TSE, see: Weisberg, Herbert (2005, ISBN:0-226-89128-3); Biemer, Paul (2010) <doi:10.1093/poq/nfq058>; Biemer, Paul et.al. (2017, ISBN:9781119041672); etc. / GPL-2	noarch
r-tsgsis	0.1	To provide a high dimensional grouped variable selection approach for detection of whole-genome SNP effects and SNP-SNP interactions, as described in Fang et al. (2017, under review). / GPL-2	noarch
r-tshrc	0.1_6	Two-stage procedure compares hazard rate functions, which may or may not cross each other. / MIT	linux-64, osx-64, win-64
r-tsmn	1.0.0	Return the first four moments of the SMN distributions (Normal, Student-t, Pearson VII, Slash or Contaminated Normal). / GPL (>= 3.0)	noarch
r-tsmode	0.6	Tools for specifying time series regression models / GPL-2	noarch
r-tsne	0.1_3	A pure R implementation of the t-SNE algorithm. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tsp	1.1.7	Basic infrastructure and some algorithms for the traveling salesperson problem (also traveling salesman problem; TSP). The package provides some simple algorithms and an interface to the Concorde TSP solver and its implementation of the Chained-Lin-Kernighan heuristic. The code for Concorde itself is not included in the package and has to be obtained separately. / GPL-3	linux-64, osx-64, win-64
r-tsqn	1.0.0	Time Series Qn is a package with applications of the Qn estimator of Rousseeuw and Croux (1993) <doi:10.1080/01621459.1993.10476408> to univariate and multivariate Time Series in time and frequency domains. More specifically, the robust estimation of autocorrelation or autocovariance matrix functions from Ma and Genton (2000, 2001) <doi:10.1111/1467-9892.00203>, <doi:10.1006/jmva.2000.1942> and Cotta (2017) <doi:10.13140/RG.2.2.14092.10883> are provided. The robust pseudo-periodogram of Molinares et. al. (2009) <doi:10.1016/j.jspi.2008.12.014> is also given. This packages also provides the M-estimator of the long-memory parameter d based on the robustification of the GPH estimator proposed by Reisen et al. (2017) <doi:10.1016/j.jspi.2017.02.008>. / GPL-2	noarch
r-tsss	1.2.4	Functions for statistical analysis, modeling and simulation of time series with state space model, based on the methodology in Kitagawa (1993, ISBN: 4-00-007703-1 and 2005, ISBN: 4-00-005455-4). / GPL-2	linux-64, osx-64, win-64
r-tstools	0.3.8	Plot official statistics' time series conveniently: automatic legends, highlight windows, stacked bar charts with positive and negative contributions, sum-as-line option, two y-axes with automatic horizontal grids that fit both axes and other popular chart types. 'tstools' comes with a plethora of defaults to let you plot without setting an abundance of parameters first, but gives you the flexibility to tweak the defaults. In addition to charts, 'tstools' provides a super fast, 'data.table' backed time series I/O that allows the user to export / import long format, wide format and transposed wide format data to various file types. / GPL-2	noarch
r-tstr	1.2	A ternary search tree is a type of prefix tree with up to three children and the ability for incremental string search. The package uses this ability for word auto-completion and spell checking. Includes a dataset with the 10001 most frequent English words. / GPL-2	noarch
r-tstutorial	1.2.3	Interactive laboratory of Time Series based in Box-Jenkins methodology. / GPL (>= 2.0)	noarch
r-tsvr	1.0.0	Tools for timescale decomposition of the classic variance ratio of community ecology. Tools are as described in Zhao et al (in prep), extending commonly used methods introduced by Peterson et al (1975) <doi: 10.2307/1936306>. / GPL-3	noarch
r-ttbbeer	1.1.0	U.S. Department of the Treasury, Alcohol and Tobacco Tax and Trade Bureau (TTB) collects data and reports on monthly beer industry production and operations. This data package includes a collection of 10 years (2006 - 2015) worth of data on materials used at U.S. breweries in pounds reported by the Brewer's Report of Operations and the Quarterly Brewer's Report of Operations forms, ready for data analysis. This package also includes historical tax rates on distilled spirits, wine, beer, champagne, and tobacco products as individual data sets. / CC0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tth	4.3.2	C source code and R wrappers for the tth/ttm TeX to HTML/MathML translators. / GPL-2	linux-64, osx-64, win-64
r-ttmoment	1.0	Computing the first two moments of the truncated multivariate t (TMVT) distribution under the double truncation. Applying the slice sampling algorithm to generate random variates from the TMVT distribution. / GPL-2	noarch
r-ttr	0.23	Functions and data to construct technical trading rules with R. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-tts	1.0	Time-Temperature Superposition analysis is often applied to frequency modulated data obtained by Dynamic Mechanic Analysis (DMA) and Rheometry in the analytical chemistry and physics areas. These techniques provide estimates of material mechanical properties (such as moduli) at different temperatures in a wider range of time. This package provides the Time-Temperature superposition Master Curve at a referred temperature by the three methods: the two wider used methods, Arrhenius based methods and WLF, and the newer methodology based on derivatives procedure. The Master Curve is smoothed by B-splines basis. The package output is composed of plots of experimental data, horizontal and vertical shifts, TTS data, and TTS data fitted using B-splines with bootstrap confidence intervals. / GPL-2	noarch
r-ttplot	1.1.1	Implementation of Time to Target plot based on the work of Ribeiro and Rosseti (2015) <DOI:10.1007/s11590-014-0760-8>, that describe a numerical method that gives the probability of an algorithm A finds a solution at least as good as a given target value in smaller computation time than algorithm B. / GPL-2	noarch
r-ttutils	1.0.1	Contains some auxiliary functions. / GPL-2	noarch
r-ttwa	0.8.5	This package makes Travel To Work Area from a commuting flow data frame. / GPL (>= 2.0)	noarch
r-tubern	0.1.0	Get statistics and reports from YouTube. To learn more about the YouTube Analytics and Reporting API, see < https://developers.google.com/youtube/reporting/ >. / MIT	noarch
r-tuckerr.mmgg	1.5.1	Performs Three-Mode Principal Components Analysis, which carries out Tucker Models. / GPL-3	noarch
r-tufte	0.5	Provides R Markdown output formats to use Tufte styles for PDF and HTML output. / GPL-3	noarch
r-tufterhandout	1.2.1	Custom template and output formats for use with rmarkdown. Produce Edward Tufte-style handouts in html formats with full support for rmarkdown features / MIT	noarch
r-tukeytrend	0.6	Provides wrapper functions to the multiple marginal model function mmm() of package ‘multcomp’ to implement the trend test of Tukey, Ciminera and Heyse (1985) <DOI:10.2307/2530666> for general parametric models. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tumblr	1.1	Provides an R-interface to the Tumblr web API (see Tumblr v2 API on https://www.tumblr.com/docs/en/api/v2). Tumblr is a microblogging platform and social networking website (https://www.tumblr.com). / Artistic-2.0	noarch
r-tunepareto	2.5	Generic methods for parameter tuning of classification algorithms using multiple scoring functions. / GPL-2	linux-64, osx-64, win-64
r-tuple	0.4_0	Functions to find all matches or non-matches, orphans, and duplicate or other replicated elements. / LGPL-3	noarch
r-turboem	2018.	Algorithms for accelerating the convergence of slow, monotone sequences from smooth, contraction mapping such as the EM and MM algorithms. It can be used to accelerate any smooth, linearly convergent acceleration scheme. A tutorial style introduction to this package is available in a vignette on the CRAN download page or, when the package is loaded in an R session, with <code>vignette(turboEM)</code> . / GPL-2	noarch
r-turtlegraphics	1.0_8	An implementation of turtle graphics < http://en.wikipedia.org/wiki/Turtle_graphics >. Turtle graphics comes from Papert's language Logo and has been used to teach concepts of computer programming. / GPL-3	noarch
r-tutorial	0.4.3	DataCamp Light (< https://github.com/datacamp/datacamp-light >) is a light-weight implementation of the DataCamp UI, that allows you to embed interactive exercises inside HTML documents. The tutorial package makes it easy to create these HTML files from R Markdown files. An extension to knitr, tutorial detects appropriately formatted code chunks and replaces them with DataCamp Light readable chunks in the resulting HTML file. / MIT	noarch
r-tuwmodel	1.0_2	The model, developed at the Vienna University of Technology, is a lumped conceptual rainfall-runoff model, following the structure of the HBV model. The model can also be run in a semi-distributed fashion. The model runs on a daily or shorter time step and consists of a snow routine, a soil moisture routine and a flow routing routine. See Parajka, J., R. Merz, G. Bloeschl (2007) <DOI:10.1002/hyp.6253> Uncertainty and multiple objective calibration in regional water balance modelling: case study in 320 Austrian catchments, Hydrological Processes, 21, 435-446. / GPL-2	linux-64, osx-64, win-64
r-tvd	0.1.0	Total Variation Denoising is a regularized denoising method which effectively removes noise from piecewise constant signals whilst preserving edges. This package contains a C implementation of Condat's very fast 1D squared error loss TVD algorithm. Additional methods and loss functions may be added in future versions. / EPL (>= 1.0)	linux-64, osx-64, win-64
r-tvsmis	0.1.1	Use a regularization likelihood method to achieve variable selection purpose. Likelihood can be worked with penalty lasso, smoothly clipped absolute deviations (SCAD), and minimax concave penalty (MCP). Tuning parameter selection techniques include cross validation (CV), Bayesian information criterion (BIC) (low and high), stability of variable selection (sVS), stability of BIC (sBIC), and stability of estimation (sEST). More details see Jiwei Zhao, Yang Yang, and Yang Ning (2018) <arXiv:1703.06379> Penalized pairwise pseudo likelihood for variable selection with nonignorable missing data. Statistica Sinica. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-tweedie	2.3.2	Maximum likelihood computations for Tweedie families, including the series expansion (Dunn and Smyth, 2005; <doi:10.1007/s11222-005-4070-y>) and the Fourier inversion (Dunn and Smyth, 2008; <doi:10.1007/s11222-007-9039-6>), and related methods. / GPL-2	linux-64, osx-64, win-64
r-twfy	0.1.0	An R wrapper around the API of TheyWorkForYou, a parliamentary monitoring site that scrapes and repackages Hansard (the UK's parliamentary record) and augments it with information from the Register of Members' Interests, election results, and voting records to provide a unified source of information about UK legislators and their activities. See < http://www.theyworkforyou.com > for details. / GPL-3	noarch
r-twiddler	0.5_0	Twiddler is an interactive tool that automatically creates a Tcl/Tk GUI for manipulating variables in any R expression. See the documentation of the function twiddle to get started. / GPL-2	noarch
r-twilio	0.1.0	The Twilio web service provides an API for computer programs to interact with telephony. The included functions wrap the SMS and MMS portions of Twilio's API, allowing users to send and receive text messages from R. See < https://www.twilio.com/docs/ > for more information. / MIT	noarch
r-twitter	1.1.9	Provides an interface to the Twitter web API. / Artistic-2.0	noarch
r-twitterwidget	0.1.1	Include the Twitter status widgets in HTML pages created using R markdown. The package uses the Twitter javascript APIs to embed in your document Twitter cards associated to specific statuses. The main targets are regular HTML pages or dashboards. / MIT	noarch
r-twocop	1.0	This package implements the nonparametric test of equality between two copulas proposed by Remillard and Scaillet in their 2009 JMVA paper. / GPL-2	linux-64, osx-64, win-64
r-twophaseind	1.1.1	Estimation of gene-treatment interactions in randomized clinical trials exploiting gene-treatment independence. / GPL-2	linux-64, osx-64, win-64
r-twosamples	1.0.0	Fast randomization based two sample tests. Testing the hypothesis that two samples come from the same distribution using randomization to create p-values. Included tests are: Kolmogorov-Smirnov, Kuiper, Cramer-von Mises, and Anderson-Darling. There is also a very efficient test based on the Wasserstein Distance. The default test 'two_sample' builds on the Wasserstein distance by using a weighting scheme like that of Anderson-Darling. We also include the permutation scheme to make test building simple for others. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-twosampletest.hd	1.0	For high-dimensional data whose main feature is a large number, p , of variables but a small sample size, the null hypothesis that the marginal distributions of p variables are the same for two groups is tested. We propose a test statistic motivated by the simple idea of comparing, for each of the p variables, the empirical characteristic functions computed from the two samples. If one rejects this global null hypothesis of no differences in distributions between the two groups, a set of permutation p -values is reported to identify which variables are not equally distributed in both groups. / GPL-2	noarch
r-twostepclogit	1.2.5	Conditional logistic regression with longitudinal follow up and individual-level random coefficients: A stable and efficient two-step estimation method. / GPL-2	noarch
r-twoway	0.6.2	Carries out analyses of two-way tables with one observation per cell, together with graphical displays for an additive fit and a diagnostic plot for removable ‘non-additivity’ via a power transformation of the response. It implements Tukey’s Exploratory Data Analysis methods, including a 1-degree-of-freedom test for row*column ‘non-additivity’, linear in the row and column effects. / GPL-3	noarch
r-txtplot	1.0_3	Provides functions to produce rudimentary ascii graphics directly in the terminal window. Provides a basic plotting function (and equivalents of curve, density, acf and barplot) as well as a boxplot function. / LGPL-3	noarch
r-types	1.0.0	Provides a simple type annotation for R that is usable in scripts, in the R console and in packages. It is intended as a convention to allow other packages to use the type information to provide error checking, automatic documentation or optimizations. / MIT	noarch
r-ubcrm	1.0.1	Two Phase I designs are implemented in the package: the classical 33 and the Continual Reassessment Method. Simulations tools are also available to estimate the operating characteristics of the methods with several user-dependent options. / GPL-2	noarch
r-ucbthesis	1.0	This package contains latex, knitr and R Markdown templates that adhere to the UC Berkeley Graduate Division’s thesis guidelines. The templates are located in the inst/ directory. / GPL-2	noarch
r-ucminf	1.1_4	An algorithm for general-purpose unconstrained non-linear optimization. The algorithm is of quasi-Newton type with BFGS updating of the inverse Hessian and soft line search with a trust region type monitoring of the input to the line search algorithm. The interface of ‘ucminf’ is designed for easy interchange with ‘optim’. / GPL-2	linux-64, osx-64, win-64
r-ucr.columnnames	0.1.0	Changes the column names of the inputted dataset to the correct names from the Uniform Crime Report codebook for the Offenses Known and Clearance by Arrest datasets from 1998-2014. / GPL-3	noarch
r-udapi	0.1.3	A client for the Urban Dictionary < http://www.urbandictionary.com/ > API. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-udderquarterinfectiondata	1.0.0	The udder quarter infection data set contains infection times of individual cow udder quarters with <i>Corynebacterium bovis</i> (Laevens et al. 1997 <DOI:10.3168/jds.S0022-0302(97)76295-7>). Obviously, the four udder quarters are clustered within a cow, and udder quarters are sampled only approximately monthly, generating interval-censored data. The data set contains both covariates that change within a cow (e.g., front and rear udder quarters) and covariates that change between cows (e.g., parity [the number of previous calvings]). The correlation between udder infection times within a cow also is of interest, because this is a measure of the infectivity of the agent causing the disease. Various models have been applied to address the problem of interdependence for right-censored event times. These models, as applied to this data set, can be found back in the publications found in the reference list. / GPL-3	noarch
r-udpipe	0.8.3	This natural language processing toolkit provides language-agnostic ‘tokenization’, ‘parts of speech tagging’, ‘lemmatization’ and ‘dependency parsing’ of raw text. Next to text parsing, the package also allows you to train annotation models based on data of ‘treebanks’ in ‘CoNLL-U’ format as provided at < http://universaldependencies.org/format.html >. The techniques are explained in detail in the paper: ‘Tokenizing, POS Tagging, Lemmatizing and Parsing UD 2.0 with UDPipe’, available at <doi:10.18653/v1/K17-3009>. / MPL-2.0	linux-64, osx-64, win-64
r-udunits2	0.13	Provides simple bindings to Unidata’s udunits library. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-ui	0.1.0	Implements functions to derive uncertainty intervals for (i) regression (linear and probit) parameters when outcome is missing not at random (non-ignorable missingness) introduced in Genbaeck, M., Stanghellini, E., de Luna, X. (2015) <doi:10.1007/s00362-014-0610-x> and Genbaeck, M., Ng, N., Stanghellini, E., de Luna, X. (2018) <doi:10.1007/s10433-017-0448-x>; and (ii) double robust and outcome regression estimators of average causal effects (on the treated) with possibly unobserved confounding introduced in Genbaeck, M., de Luna, X. (2018) <doi:10.1111/biom.13001>. / GPL-2	noarch
r-uiucthemes	0.2.1	A set of custom ‘R’ ‘Markdown’ templates for documents and presentations with the University of Illinois at Urbana-Champaign (UIUC) color scheme and identity standards. / MIT	noarch
r-ukbabynames	0.1.1	Full listing of UK baby names occurring more than three times per year between 1996 and 2015, and rankings of baby name popularity by decade from 1904 to 1994. / CC0	noarch
r-ukgasapi	0.16	Allows users to access live UK gas market information via National Grid’s API. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-ulid	0.3.0	Universally unique identifiers ('UUIDs') can be suboptimal for many use-cases because they aren't the most character efficient way of encoding 128 bits of randomness; v1/v2 versions are impractical in many environments, as they require access to a unique, stable MAC address; v3/v5 versions require a unique seed and produce randomly distributed IDs, which can cause fragmentation in many data structures; v4 provides no other information than randomness which can cause fragmentation in many data structures. 'ULIDs' (< https://github.com/ulid/spec >) have 128-bit compatibility with 'UUID', 1.21e24 unique 'ULIDs' per millisecond, are lexicographically sortable, canonically encoded as a 26 character string, as opposed to the 36 character 'UUID', use Crockford's 'base32' for better efficiency and readability (5 bits per character), are case insensitive, have no special characters (i.e. are 'URL' safe) and have a monotonic sort order (correctly detects and handles the same millisecond). / MIT	linux-64, osx-64, win-64
r-ultimixt	2.1	A generic reference Bayesian analysis of unidimensional mixture distributions obtained by a location-scale parameterisation of the model is implemented. The including functions simulate and summarize posterior samples for location-scale mixture models using a weakly informative prior. There is no need to define priors for scale-location parameters except two hyperparameters in which are associated with a Dirichlet prior for weights and a simplex. / GPL (>= 2.0)	noarch
r-umoments	0.1.0	Calculates one-sample unbiased central moment estimates and two-sample pooled estimates up to 6th order, including unbiased estimates of powers and products of central moments. Provides the machinery for obtaining unbiased central moment estimators beyond 6th order. / GPL-2	noarch
r-ump	0.5_8	Does uniformly most powerful (UMP) and uniformly most powerful unbiased (UMPU) tests. At present only distribution implemented is binomial distribution. Also does fuzzy tests and confidence intervals (following Geyer and Meeden, 2005, <doi:10.1214/088342305000000340>) for the binomial distribution (one-tailed procedures based on UMP test and two-tailed procedures based on UMPU test). / MIT	linux-64, osx-64, win-64
r-umpire	1.3.7	The Ultimate Microarray Prediction, Reality and Inference Engine (UMPIRE) is a package to facilitate the simulation of realistic microarray data sets with link to associate outcomes. See Zhang and Coombes (2012) <doi:10.1186/1471-2105-13-S13-S1>. / Apache License (== 2.0)	noarch
r-unbalhaar	2.0	The package implements top-down and bottom-up algorithms for nonparametric function estimation in Gaussian noise using Unbalanced Haar wavelets. / GPL-2	noarch
r-uncdecomp	0.0.4	If a procedure consists of several stages and there are several scenarios that can be selected for each stage, uncertainty of the procedure can be decomposed by stages or scenarios. cum_uncertainty() is used to decompose uncertainty based on the cumulative uncertainty. stage_uncertainty() and scenario_uncertainty() is used to decompose uncertainty based on the second order interaction ANOVA model. In stage_uncertainty() and scenario_uncertainty(), the uncertainty from interaction effect from two stages is distributed equally to each stage. / GPL-2	noarch
r-unf	2.0.6	Computes a universal numeric fingerprint (UNF) for an R data object. UNF is a cryptographic hash or signature that can be used to uniquely identify (a version of) a rectangular dataset, or a subset thereof. UNF can be used, in tandem with a DOI, to form a persistent citation to a versioned dataset. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-unfoldr	0.7	Stereological unfolding of the joint size-shape-orientation distribution of spheroidal shaped particles. / GPL-3	linux-64, osx-64, win-64
r-unicode	12.0.0	Data from Unicode 12.0.0 and related utilities. / GPL-2	noarch
r-unidoe	1.0.2	Efficient procedures for constructing uniform design of experiments under various space-filling criteria. It is based on a stochastic and adaptive threshold accepting algorithm with flexible initialization, adaptive threshold, and stochastic evolution. The package may also construct the augmented uniform designs in a sequential manner. / GPL-3	linux-64, osx-64, win-64
r-unifed	1.1.1	Probability functions and family for glm() of the unified distribution (Quijano Xacur, 2018; <arXiv:1812.00251>). / GPL-3	linux-64, osx-64, win-64
r-unisoregression	0.0_0	Perform L1 or L2 isotonic and unimodal regression on 1D weighted or unweighted input vector and isotonic regression on 2D weighted or unweighted input vector. It also performs L infinity isotonic and unimodal regression on 1D unweighted input vector. Reference: Quentin F. Stout (2008) <doi:10.1016/j.csda.2008.08.005>. Spouge, J., Wan, H. & Wilbur, W.(2003) <doi:10.1023/A:1023901806339>. Q.F. Stout (2013) <doi:10.1007/s00453-012-9628-4>. / GPL-2	linux-64, osx-64, win-64
r-unikn	0.1.0	Define and use graphical elements of corporate design manuals in R. The ‘unikn’ package provides color functions (by defining dedicated colors and color palettes, and commands for changing, viewing, and using them) and styled text elements (e.g., for marking, underlining, or plotting colored titles). The pre-defined range of colors and text functions is based on the corporate design of the University of Konstanz < https://www.uni-konstanz.de/ >, but can be adapted and extended for other institutions and purposes. / CC BY-SA 4.0	noarch
r-unine	0.2.0	Implementation of light stemmers for French, German, Italian, Spanish, Portuguese, Finnish, Swedish. They are based on the same work as the light stemmers found in ‘SolR’ < https://lucene.apache.org/solr/ > or ‘ElasticSearch’ < https://www.elastic.co/fr/products/elasticsearch >. A light stemmer consists in removing inflections only for noun and adjectives. Indexing verbs for these languages is not of primary importance compared to nouns and adjectives. The stemming procedure for French is described in (Savoy, 1999) <doi:10.1002/(SICI)1097-4571(1999)50:10%3C944::AID-ASI9%3E3.3.CO;2-H>. / MIT	linux-64, osx-64, win-64
r-uniqtag	1.0	For each string in a set of strings, determine a unique tag that is a substring of fixed size k unique to that string, if it has one. If no such unique substring exists, the least frequent substring is used. If multiple unique substrings exist, the lexicographically smallest substring is used. This lexicographically smallest substring of size k is called the UniqTag of that string. / MIT	noarch
r-unitcircle	0.1.3	The uc.check() function checks whether the roots of a given polynomial lie outside the Unit circle. You can also easily draw an unit circle. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-unitedr	0.3.1	United is a software tool which can be downloaded at the following web-site < http://www.schroepl.net/pbm/software/united/ >. In general, it is a virtual manager game for football teams. This package contains helpful functions for determining an optimal formation for a virtual match in United. E.g. knowing that the opponent has a strong defensive it is advisable to beat him in the mid-field. Furthermore, this package contains functions for computing the optimal usage of hardness in a game. / GPL-2	noarch
r-unitizer	1.4.8	Simplifies regression tests by comparing objects produced by test code with earlier versions of those same objects. If objects are unchanged the tests pass, otherwise execution stops with error details. If in interactive mode, tests can be reviewed through the provided interactive environment. / GPL-2	noarch
r-units	0.6_2	Support for measurement units in R vectors, matrices and arrays: automatic propagation, conversion, derivation and simplification of units; raising errors in case of unit incompatibility. Compatible with the POSIXct, Date and diff-time classes. Uses the UNIDATA udunits library and unit database for unit compatibility checking and conversion. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-unittest	1.3_0	Concise TAP < http://testanything.org/ > compliant unit testing package. Authored tests can be run using CMD check with minimal implementation overhead. / GPL-3	noarch
r-univrng	1.2	Pseudo-random number generation of 17 univariate distributions. / GPL-2 GPL-3	noarch
r-unix	1.5	Bindings to system utilities found in most Unix systems such as POSIX functions which are not part of the Standard C Library. / MIT	linux-64, osx-64
r-unmarked	0.12_3	Fits hierarchical models of animal abundance and occurrence to data collected using survey methods such as point counts, site occupancy sampling, distance sampling, removal sampling, and double observer sampling. Parameters governing the state and observation processes can be modeled as functions of covariates. / GPL-3	linux-64, osx-64, win-64
r-unrepx	1.0	Provides half-normal plots, reference plots, and Pareto plots of effects from an unreplicated experiment, along with various pseudo-standard-error measures, simulated reference distributions, and other tools. Many of these methods are described in Daniel C. (1959) <doi:10.1080/00401706.1959.10489866> and/or Lenth R.V. (1989) <doi:10.1080/00401706.1989.10488595>, but some new approaches are added and integrated in one package. / GPL-2	noarch
r-unsystation	0.2.0	Performs a test for second-order stationarity of time series based on unsystematic sub-samples. / GPL-2	linux-64, osx-64, win-64
r-unvotes	0.2.0	Historical voting data of the United Nations General Assembly. This includes votes for each country in each roll call, as well as descriptions and topic classifications for each vote. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-upsvarapprox	0.1.1	Variance approximations for the Horvitz-Thompson total estimator in Unequal Probability Sampling using only first-order inclusion probabilities. See Matei and Tillä© (2005) and Haziza, Mecatti and Rao (2008) for details. / GPL-3	noarch
r-uptimerobot	1.0.0	Provide a set of wrappers to call all the endpoints of UptimeRobot API which includes various kind of ping, keep-alive and speed tests. See < https://uptimerobot.com/ > for more information. / MIT	noarch
r-urbin	0.1_8	Calculate unified measures that quantify the effect of a covariate on a binary dependent variable (e.g., for meta-analyses). This can be particularly important if the estimation results are obtained with different models/estimators (e.g., linear probability model, logit, probit, ...) and/or with different transformations of the explanatory variable of interest (e.g., linear, quadratic, interval-coded, ...). The calculated unified measures are: (a) semi-elasticities of linear, quadratic, or interval-coded covariates and (b) effects of linear, quadratic, interval-coded, or categorical covariates when a linear or quadratic covariate changes between distinct intervals, the reference category of a categorical variable or the reference interval of an interval-coded variable needs to be changed, or some categories of a categorical covariate or some intervals of an interval-coded covariate need to be grouped together. Approximate standard errors of the unified measures are also calculated. All methods that are implemented in this package are described in the 'vignette' Extracting and Unifying Semi-Elasticities and Effect Sizes from Studies with Binary Dependent Variables that is included in this package. / GPL-2	noarch
r-urca	1.3_0	Unit root and cointegration tests encountered in applied econometric analysis are implemented. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-uroot	2.0_9	Seasonal unit roots and seasonal stability tests. P-values based on response surface regressions are available for both tests. P-values based on bootstrap are available for seasonal unit root tests. A parallel implementation of the bootstrap method requires a CUDA capable GPU with compute capability >= 3.0, otherwise a debugging version fully coded in R is used. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
r-usaboundaries	0.3.1	The boundaries for geographical units in the United States of America contained in this package include state, county, congressional district, and zip code tabulation area. Contemporary boundaries are provided by the U.S. Census Bureau (public domain). Historical boundaries for the years from 1629 to 2000 are provided form the Newberry Library's 'Atlas of Historical County Boundaries' (licensed CC BY-NC-SA). Additional data is provided in the 'US-AboundariesData' package; this package provides an interface to access that data. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-uscensus2000cdp	0.03	US Census 2000 Designated Places shapefiles and additional demographic data from the SF1 100 percent files. This data set contains polygon files in lat/lon coordinates and the corresponding demographic data for a number of different variables. / GPL-2	noarch
r-uscensus2000tract	0.03	US 2000 Census Tract shapefiles and additional demographic data from the SF1 100 percent files. This data set contains polygon files in lat/lon coordinates and the corresponding demographic data for a number of different variables. / GPL-2	noarch
r-uscensus2010	0.11	US Census 2010 shape files and additional demographic data from the SF1 100 percent files. This package contains a number of helper functions for the US-census2010blk, UScensus2010blkgrp, UScensus2010tract, UScensus2010cdp packages. / GPL-2	noarch
r-usdm	1.1_18	This is a framework that aims to provide methods and tools for assessing the impact of different sources of uncertainties (e.g. positional uncertainty) on performance of species distribution models (SDMs.) / GPL-3	noarch
r-usedist	0.1.0	Functions to re-arrange, extract, and work with distances. / GPL-3	noarch
r-usethis	1.5.0	Automate package and project setup tasks that are otherwise performed manually. This includes setting up unit testing, test coverage, continuous integration, Git, 'GitHub', licenses, 'Rcpp', 'RStudio' projects, and more. / GPL-3	noarch
r-usgsstates2k	1.0.1	A map of the USA from the United States Geological Survey (USGS). Irucka worked with this data set while a Cherokee Nation Technology Solutions (CNTS) USGS Contractor and/or USGS employee. It is replaced by 'states2k'. / CC0	noarch
r-usmap	0.4.0	Obtain United States map data frames of varying region types (e.g. county, state). The map data frames include Alaska and Hawaii conveniently placed to the bottom left, as they appear in most maps of the US. Convenience functions for plotting choropleths and working with FIPS codes are also provided. / GPL-3	noarch
r-ustatbookabsc	1.0.0	A set of functions leading to multivariate response L1 regression. This includes functions on computing Euclidean inner products and norms, weighted least squares estimates on multivariate responses, function to compute fitted values and residuals. This package is a companion to the book U-Statistics, M-estimation and Resampling, by Arup Bose and Snigdhanu Chatterjee, to appear in 2017 as part of the Texts and Readings in Mathematics (TRIM) series of Hindustan Book Agency and Springer-Verlag. / GPL-3	noarch
r-ustyc	1.0.0	Forms a query to submit for US Treasury yield curve data, posting this query to the US Treasury web site's data feed service. By default the download includes data yield data for 12 products from January 1, 1990, some of which are NA during this span. The caller can pass parameters to limit the query to a certain year or year and month, but the full download is not especially large. The download data from the service is in XML format. The package's main function transforms that XML data into a numeric data frame with treasury product items (constant maturity yields for 12 kinds of bills, notes, and bonds) as columns and dates as row names. The function returns a list which includes an item for this data frame as well as query-related values for reference and the update date from the service. / MIT	noarch
r-utc	0.1.5	Three functions are provided: first function changes time from local to UTC, other changes from UTC to local and third returns difference between local and UTC. %h% operator is also provided it adds hours to a time. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-utf8	1.1.4	Process and print ‘UTF-8’ encoded international text (Unicode). Input, validate, normalize, encode, format, and display. / Apache License (== 2.0) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-utility	1.4.3	Construct and plot objective hierarchies and associated value and utility functions. Evaluate the values and utilities and visualize the results as colored objective hierarchies or tables. Visualize uncertainty by plotting median and quantile intervals within the nodes of objective hierarchies. Get numerical results of the evaluations in standard R data types for further processing. / GPL-3	noarch
r-uuid	0.1_2	Tools for generating and handling of UUIDs (Universally Unique Identifiers). / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-v8	2.3	An R interface to Google’s open source JavaScript engine. This package can now be compiled either with V8 version 6 or 7 (LTS) from nodejs or with the legacy 3.14/3.15 branch of V8. / MIT	win-64
r-vaersndvax	1.0.4	Non-Domestic VAERS vaccine data for 01/01/2016 - 06/14/2016. If you want to explore the full VAERS data for 1990 - Present (data, symptoms, and vaccines), then check out the ‘vaersND’ package from the URL below. The URL and BugReports below correspond to the ‘vaersND’ package, of which ‘vaersNDvax’ is a small subset (2016 only). ‘vaersND’ is not hosted on CRAN due to the large size of the data set. To install the Suggested ‘vaers’ and ‘vaersND’ packages, use the following R code: ‘devtools::install_git(https://gitlab.com/iembry/vaers.git , build_vignettes = TRUE)’ and ‘devtools::install_git(https://gitlab.com/iembry/vaersND.git , build_vignettes = TRUE)’. VAERS is a national vaccine safety surveillance program co-sponsored by the US Centers for Disease Control and Prevention (CDC) and the US Food and Drug Administration (FDA). VAERS is a post-marketing safety surveillance program, collecting information about adverse events (possible side effects) that occur after the administration of vaccines licensed for use in the United States. For more information about the data, visit < https://vaers.hhs.gov/index >. For information about vaccination/immunization hazards, visit < http://www.questionuniverse.com/rethink.html/#vaccine >. / CC0	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vaersvax	1.0.5	US VAERS vaccine data for 01/01/2018 - 06/14/2018. If you want to explore the full VAERS data for 1990 - Present (data, symptoms, and vaccines), then check out the 'vaers' package from the URL below. The URL and BugReports below correspond to the 'vaers' package, of which 'vaersvax' is a small subset (2018 only). 'vaers' is not hosted on CRAN due to the large size of the data set. To install the Suggested 'vaers' and 'vaersND' packages, use the following R code: 'devtools::install_git(< https://gitlab.com/iembry/vaers.git >, build_vignettes = TRUE)' and 'devtools::install_git(< https://gitlab.com/iembry/vaersND.git >, build_vignettes = TRUE)'. The Vaccine Adverse Event Reporting System (VAERS) is a national early warning system to detect possible safety problems in U.S.-licensed vaccines. VAERS is co-managed by the Centers for Disease Control and Prevention (CDC) and the U.S. Food and Drug Administration (FDA). For more information about the data, visit < https://vaers.hhs.gov/ >. For information about vaccination/immunization hazards, visit < http://www.questionuniverse.com/rethink.html#vaccine >. / CC0	noarch
r-valaddin	1.0.0	A set of basic tools to transform functions into functions with input validation checks, in a manner suitable for both programmatic and interactive use. / MIT	noarch
r-valection	1.0.0	A binding for the 'valection' program which offers various ways to sample the outputs of competing algorithms or parameterizations, and fairly assess their performance against each other. The 'valection' C library is required to use this package and can be downloaded from: < http://labs.oicr.on.ca/boutros-lab/software/valection >. Cooper CI, et al; Valection: Design Optimization for Validation and Verification Studies; Biorxiv 2018; <doi:10.1101/254839>. / GPL-3	noarch
r-valetr	0.1.0	Interface to Bank of Canada's 'Valet' API (< https://www.bankofcanada.ca/valet/docs >). Please read the API terms and conditions: < https://www.bankofcanada.ca/terms/ >. / GPL-3	noarch
r-validatejsonr	1.0.4	The current implementation uses the C library 'RapidJSON' to supply the schema functionality, it supports JSON Schema Draft v4. As of 2016-09-09, 'RapidJSON' passed 262 out of 263 tests in JSON Schema Test Suite (JSON Schema draft 4). / BSD_2_clause	linux-64, osx-64, win-64
r-valorate	1.0.1	The algorithm implemented in this package was designed to quickly estimate the distribution of the log-rank especially for heavy unbalanced groups. VALORATE estimates the null distribution and the p-value of the log-rank test based on a recent formulation. For a given number of alterations that define the size of survival groups, the estimation involves a weighted sum of distributions that are conditional on a co-occurrence term where mutations and events are both present. The estimation of conditional distributions is quite fast allowing the analysis of large datasets in few minutes < http://bioinformatica.mty.itesm.mx/valorate >. / GPL-2	linux-64, osx-64, win-64
r-valottery	0.0.1	Historical results for the state of Virginia lottery draw games. Data were downloaded from https://www.valottery.com/ . / CC0	noarch
r-var.etp	0.7	Estimation, Hypothesis Testing, Prediction for Stationary Vector Autoregressive Models / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-varband	0.9.0	Implementation of the variable banding procedure for modeling local dependence and estimating precision matrices that is introduced in Yu & Bien (2016) and is available at < https://arxiv.org/abs/1604.07451 >. / GPL-3	linux-64, osx-64, win-64
r-varbin	0.2.1	Tool for easy and efficient discretization of continuous and categorical data. The package calculates the most optimal binning of a given explanatory variable with respect to a user-specified target variable. The purpose is to assign a unique Weight-of-Evidence value to each of the calculated binpoints in order to recode the original variable. The package allows users to impose certain restrictions on the functional form on the resulting binning while maximizing the overall information value in the original data. The package is well suited for logistic scoring models where input variables may be subject to restrictions such as linearity by e.g. regulatory authorities. An excellent source describing in detail the development of scorecards, and the role of Weight-of-Evidence coding in credit scoring is (Siddiqi 2006, ISBN: 978-0-471-75451-0). The package utilizes the discrete nature of decision trees and Isotonic Regression to accommodate the trade-off between flexible functional forms and maximum information value. / GPL-2	noarch
r-variag	0.2_1	Interactive variogram diagnostics. / GPL-2	noarch
r-vared	1.0.0	Generating functions for both optimal and ordinary difference sequences, and the difference-based estimation functions. / GPL-2	noarch
r-vares	1.0	Computes Value at risk and expected shortfall, two most popular measures of financial risk, for over one hundred parametric distributions, including all commonly known distributions. Also computed are the corresponding probability density function and cumulative distribution function. / GPL-2	noarch
r-varhandle	2.0.3	Variables are the fundamental parts of each programming language but handling them might be frustrating for programmers from time to time. This package contains some functions to help user (especially data explorers) to make more sense of their variables and take the most out of variables and hardware resources. These functions are written, collected and crafted over 5 years of experience in statistical data analysis on high-dimensional data and for each of them there was a need. Functions in this package are suppose to be efficient and easy to use, hence they will be frequently updated to make them more convenient. / GPL-2	noarch
r-variables	1.0_2	Abstract descriptions of (yet) unobserved variables. / GPL-2	noarch
r-vars	1.5_3	Estimation, lag selection, diagnostic testing, forecasting, causality analysis, forecast error variance decomposition and impulse response functions of VAR models and estimation of SVAR and SVEC models. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-varsedig	1.9	An algorithm which identifies the morphometric features that significantly discriminate two taxa and validates the morphological distinctness between them via a Monte-Carlo test, polar coordinates and overlap of the area under the density curve. / GPL-2	noarch
r-varsel	0.1	Feature selection using Sequential Forward Floating feature Selection and Jeffries-Matusita distance. It returns a suboptimal set of features to use for image classification. Reference: Dalponte, M., Oerka, H.O., Gobakken, T., Gianelle, D. & Naesset, E. (2013). Tree Species Classification in Boreal Forests With Hyperspectral Data. IEEE Transactions on Geoscience and Remote Sensing, 51, 2632-2645, <DOI:10.1109/TGRS.2012.2216272>. / GPL-3	noarch
r-varselrf	0.7_8	Variable selection from random forests using both backwards variable elimination (for the selection of small sets of non-redundant variables) and selection based on the importance spectrum (somewhat similar to scree plots; for the selection of large, potentially highly-correlated variables). Main applications in high-dimensional data (e.g., microarray data, and other genomics and proteomics applications). / GPL-2	noarch
r-varswapprice	1.0	Computes a portfolio of European options that replicates the cost of capturing the realised variance of an equity index. / GPL-3	noarch
r-vbdm	0.0.4	Efficient algorithm for solving discrete mixture regression model for rare variant association analysis. Uses variational Bayes algorithm to efficiently search over model space. Outputs an approximate likelihood ratio test as well as variant level posterior probabilities of association. / GPL-2	linux-64, osx-64, win-64
r-vbsr	0.0.5	Efficient algorithm for solving ultra-sparse regularized regression models using a variational Bayes algorithm with a spike (l0) prior. Algorithm is solved on a path, with coordinate updates, and is capable of generating very sparse models. There are very general model diagnostics for controlling type-1 error included in this package. / GPL-2	linux-64, osx-64, win-64
r-vca	1.4.0	ANOVA and REML estimation of linear mixed models is implemented, once following Searle et al. (1991, ANOVA for unbalanced data), once making use of the 'lme4' package. The primary objective of this package is to perform a variance component analysis (VCA) according to CLSI EP05-A3 guideline Evaluation of Precision of Quantitative Measurement Procedures (2014). There are plotting methods for visualization of an experimental design, plotting random effects and residuals. For ANOVA type estimation two methods for computing ANOVA mean squares are implemented (SWEEP and quadratic forms). The covariance matrix of variance components can be derived, which is used in estimating confidence intervals. Linear hypotheses of fixed effects and LS means can be computed. LS means can be computed at specific values of covariables and with custom weighting schemes for factor variables. See ?VCA for a more comprehensive description of the features. / GPL-3	linux-64, osx-64, win-64
r-vcd	1.4_4	Visualization techniques, data sets, summary and inference procedures aimed particularly at categorical data. Special emphasis is given to highly extensible grid graphics. The package was package was originally inspired by the book Visualizing Categorical Data by Michael Friendly and is now the main support package for a new book, Discrete Data Analysis with R by Michael Friendly and David Meyer (2015). / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vcov	0.0.1	Methods for faster extraction (about 5x faster in a few test cases) of variance-covariance matrices and standard errors from models. Methods in the ‘stats’ package tend to rely on the summary method, which may waste time computing other summary statistics which are summarily ignored. / GPL-2	noarch
r-vcvcomp	1.0.1	Comparison of variance - covariance patterns using relative principal component analysis (relative eigenanalysis). Also provides functions to compute group covariance matrices, distance matrices, and perform proportionality tests. A working sample on the body shape of cichlid fishes is included. / GPL-3	noarch
r-vdgraph	2.2_2	Uses a modification of the published FORTRAN code in A Computer Program for Generating Variance Dispersion Graphs by G. Vining, Journal of Quality Technology, Vol. 25 No. 1 January 1993, to produce variance dispersion graphs. Also produces fraction of design space plots, and contains data frames for several minimal run response surface designs. / GPL-2	linux-64, osx-64, win-64
r-vdgermlines	0.1	Contains variable, diversity, and joining sequences and accompanying functions that enable both the extraction of and comparison between immune V-D-J genomic segments from a variety of species. Sources include IMGT from MP Lefranc (2009) <doi:10.1093/nar/gkn838> and Vgenerepertoire from publication DN Olivieri (2014) <doi:10.1007/s00251-014-0784-3>. / GPL-2	noarch
r-vdspcalibration	1.0	Provides statistical methods for the design and analysis of a calibration study, which aims for calibrating measurements using two different methods. The package includes sample size calculation, sample selection, regression analysis with error-in measurements and change-point regression. The method is described in Tian, Durazo-Arvizu, Myers, et al. (2014) <DOI:10.1002/sim.6235>. / GPL-3	noarch
r-vec2dtransf	1.1	A package for applying affine and similarity transformations on vector spatial data (sp objects). Transformations can be defined from control points or directly from parameters. If redundant control points are provided Least Squares is applied allowing to obtain residuals and RMSE. / GPL-2	noarch
r-vecsets	1.2.1	The base ‘sets’ tools follow the algebraic definition that each element of a set must be unique. Since it’s often helpful to compare all elements of two vectors, this toolset treats every element as unique for counting purposes. For ease of use, all functions in vecsets have an argument ‘multiple’ which, when set to FALSE, reverts them to the base::set tools functionality. / LGPL-3	noarch
r-vecstatgraphs2d	1.8	A 2D statistical analysis is performed, both numerical and graphical, of a set of vectors. Since a vector has two components (module and azimuth) vector analysis is performed in three stages: modules are analyzed by means of linear statistics, azimuths are analyzed by circular statistics, and the joint analysis of modules and azimuths is done using density maps that allow detecting another distribution properties (i.e. anisotropy) and outliers. Tests and circular statistic parameters have associated a full range of graphing: histograms, maps of distributions, point maps, vector maps, density maps, distribution modules and azimuths. / GPL-3	noarch
r-vegalite	0.6.1	The ‘Vega-Lite’ ‘JavaScript’ framework provides a higher-level grammar for visual analysis, akin to ‘ggplot’ or ‘Tableau’, that generates complete ‘Vega’ specifications. Functions exist which enable building a valid ‘spec’ from scratch or importing a previously created ‘spec’ file. Functions also exist to export ‘spec’ files and to generate code which will enable plots to be embedded in properly configured web pages. The default behavior is to generate an ‘htmlwidget’. / AGPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vegawidget	0.2.1	‘Vega’ and ‘Vega-Lite’ parse text in ‘JSON’ notation to render chart-specifications into ‘HTML’. This package is used to facilitate the rendering. It also provides a means to interact with signals, events, and datasets in a ‘Vega’ chart using ‘JavaScript’ or ‘Shiny’. / MIT	noarch
r-vegdata	0.9.5	Handling of vegetation data from different sources (Turboveg < http://www.synbiosys.alterra.nl/turboveg/ >; the German national repository < http://www.vegetweb.de > and others. Taxonomic harmonization (given appropriate taxonomic lists, e.g. the German taxonomic standard list GermanSL, < http://germansl.infinitemature.org >). / GPL-2	noarch
r-vegetarian	1.2	This package computes diversity for community data sets using the methods outlined by Jost (2006, 2007). While there are differing opinions on the ideal way to calculate diversity (e.g. Magurran 2004), this method offers the advantage of providing diversity numbers equivalents, independent alpha and beta diversities, and the ability to incorporate ‘order’ (q) as a continuous measure of the importance of rare species in the metrics. The functions provided in this package largely correspond with the equations offered by Jost in the cited papers. The package computes alpha diversities, beta diversities, gamma diversities, and similarity indices. Confidence intervals for diversity measures are calculated using a bootstrap method described by Chao et al. (2008). For datasets with many samples (sites, plots), sim.table creates tables of all pairwise comparisons possible, and for grouped samples sim.groups calculates pairwise combinations of within- and between-group comparisons. / GPL-2	noarch
r-vegperiod	0.2.6	Collection of common methods to determine growing season length in a simple manner. Start and end dates of the vegetation periods are calculated solely based on daily mean temperatures and the day of the year. / GPL-3	noarch
r-vembedr	0.1.3	A set of functions for generating HTML to embed hosted video in your R Markdown documents or Shiny applications. / MIT	noarch
r-venn	1.7	Draws and displays Venn diagrams up to 7 sets, and any Boolean union of set intersections. / GPL-2	noarch
r-venneuler	1.1_0	Calculates and displays Venn and Euler Diagrams / MPL-1.1	noarch
r-versions	0.3	Installs specified versions of R packages hosted on CRAN and provides functions to list available versions and the versions of currently installed packages. These tools can be used to help make R projects and packages more reproducible. ‘versions’ fits in the narrow gap between the ‘devtools’ install_version() function and the ‘checkpoint’ package. devtools::install_version() installs a stated package version from source files stored on the CRAN archives. However CRAN does not store binary versions of packages so Windows users need to have RTools installed and Windows and OSX users get longer installation times. ‘checkpoint’ uses the Revolution Analytics MRAN server to install packages (from source or binary) as they were available on a given date. It also provides a helpful interface to detect the packages in use in a directory and install all of those packages for a given date. ‘checkpoint’ doesn’t provide install.packages-like functionality however, and that’s what ‘versions’ aims to do, by querying MRAN. As MRAN only goes back to 2014-09-17, ‘versions’ can’t install packages archived before this date. / BSD_3_clause	noarch
r-vertexsimilarity	0.1	Creates Vertex Similarity matrix of an undirected graph based on the method stated by E. A. Leicht, Petter Holme, AND M. E. J. Newman in their paper <DOI:10.1103/PhysRevE.73.026120>. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-verylargeintegers	0.1.6	Multi-precision library that allows to store and operate with arbitrarily big integers without loss of precision. It includes a large list of tools to work with them, like: - Arithmetic and logic operators - Modular-arithmetic operators - Computer Number Theory utilities - Probabilistic primality tests - Factorization algorithms - Random generators of different types of integers. / GPL-3	linux-64, osx-64, win-64
r-vetr	0.2.7	Declarative template-based framework for verifying that objects meet structural requirements, and auto-composing error messages when they do not. / GPL-2	linux-64, osx-64, win-64
r-vfprogression	0.7.1	Realization of published methods to analyze visual field (VF) progression. Introduction to the plotting methods (designed by author TE) for VF output visualization. A sample dataset for two eyes, each with 10 follow-ups is included. The VF analysis methods could be found in – Musch et al. (1999) <doi:10.1016/S0161-6420(99)90147-1>, Nouri-Mahdavi et al. (2012) <doi:10.1167/iovs.11-9021>, Schell et al. (2014) <doi:10.1016/j.ophtha.2014.02.021>, Aptel et al. (2015) <doi:10.1111/aos.12788>. / GPL-2	noarch
r-vgam	1.1_1	An implementation of about 6 major classes of statistical regression models. At the heart of it are the vector generalized linear and additive model (VGLM/VGAM) classes, and the book Vector Generalized Linear and Additive Models: With an Implementation in R (Yee, 2015) <DOI:10.1007/978-1-4939-2818-7> gives details of the statistical framework and VGAM package. Currently only fixed-effects models are implemented, i.e., no random-effects models. Many (150) models and distributions are estimated by maximum likelihood estimation (MLE) or penalized MLE, using Fisher scoring. VGLMs can be loosely thought of as multivariate GLMs. VGAMs are data-driven VGLMs (i.e., with smoothing). The other classes are RR-VGLMs (reduced-rank VGLMs), quadratic RR-VGLMs, reduced-rank VGAMs, RCIMs (row-column interaction models)—these classes perform constrained and unconstrained quadratic ordination (CQO/UQO) models in ecology, as well as constrained additive ordination (CAO). Note that these functions are subject to change; see the NEWS and ChangeLog files for latest changes. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-vgamdata	1.0_3	Data sets to accompany the VGAM package and the book Vector Generalized Linear and Additive Models: With an Implementation in R (Yee, 2015) <DOI:10.1007/978-1-4939-2818-7>. These are used to illustrate vector generalized linear and additive models (VGLMs/VGAMs), and associated models (Reduced-Rank VGLMs, Quadratic RR-VGLMs, Row-Column Interaction Models, and constrained and unconstrained ordination models in ecology). / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vgamextra	0.0.1	Extending the functionalities of the ‘VGAM’ package with additional functions and datasets. At present, ‘VGAMextra’ comprises new family functions (ffs) to estimate several time series models by maximum likelihood using Fisher scoring, unlike popular packages in CRAN relying on <code>optim()</code> , including ARMA-GARCH-like models, the Order-(p, d, q) ARIMAX model (non-seasonal), the Order-(p) VAR model, error correction models for cointegrated time series, and ARMA-structures with Student-t errors. For independent data, new ffs to estimate the inverse- Weibull, the inverse-gamma, the generalized beta of the second kind and the general multivariate normal distributions are available. In addition, ‘VGAMextra’ incorporates new VGLM-links for the mean-function, and the quantile-function (as an alternative to ordinary quantile modelling) of several 1-parameter distributions, that are compatible with the class of VGLM/VGAM family functions. Currently, only fixed-effects models are implemented. All functions are subject to change; see the NEWS for further details on the latest changes. / GPL-2	linux-64, osx-64, win-64
r-vhclassification	0.3	This package provides an implementation of Linear discriminant analysis and quadratic discriminant analysis that works fine in very high dimension (when there are many more variables than observations). / GPL-2	noarch
r-vhica	0.2.4	The Vertical and Horizontal Inheritance Consistence Analysis method is described in the following publication: VHICA: a new method to discriminate between vertical and horizontal transposon transfer: application to the mariner family within <i>Drosophila</i> by G. Wallau. et al. (2016) <DOI:10.1093/molbev/msv341>. The purpose of the method is to detect horizontal transfers of transposable elements, by contrasting the divergence of transposable element sequences with that of regular genes. / GPL-2	noarch
r-vicmodel	0.1.2	The Variable Infiltration Capacity (VIC) model is a macroscale hydrologic model that solves full water and energy balances, originally developed by Xu Liang at the University of Washington (UW). The version of VIC source code used is of 5.0.1 on < https://github.com/UW-Hydro/VIC/ >, see Hamman et al. (2018). Development and maintenance of the current official version of the VIC model at present is led by the UW Hydro (Computational Hydrology group) in the Department of Civil and Environmental Engineering at UW. VIC is a research model and in its various forms it has been applied to most of the major river basins around the world, as well as globally. If you make use of this model, please acknowledge the appropriate references listed in the help page of this package or on the references page < http://vic.readthedocs.io/en/master/Documentation/References/ > of the VIC official documentation website. These should include Liang et al. (1994) plus any references relevant to the features you are using Reference: Liang, X., D. P. Lettenmaier, E. F. Wood, and S. J. Burges (1994), A simple hydrologically based model of land surface water and energy fluxes for general circulation models, <i>J. Geophys. Res.</i> , 99(D7), 14415-14428, <doi:10.1029/94JD00483>. Hamman et al. (2018) about VIC 5.0.1 also can be considered: Hamman, J. J., Nijssen, B., Bohn, T. J., Gergel, D. R., and Mao, Y. (2018), The Variable Infiltration Capacity model version 5 (VIC-5): infrastructure improvements for new applications and reproducibility, <i>Geosci. Model Dev.</i> , 11, 3481-3496, <doi:10.5194/gmd-11-3481-2018>. / GPL-3	linux-64, osx-64, win-64
r-vietnamcode	0.1.1	Converts Vietnam’s provinces’ names and ID across different formats. Handles diacritics and different spellings. / GPL-3	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vif	1.0	This package implements a fast regression algorithm for building linear model for large data as defined in the paper VIF-Regression: A Fast Regression Algorithm for Large Data (2011), Journal of the American Statistical Association, Vol. 106, No. 493: 232-247 by Dongyu Lin, Dean P. Foster, and Lyle H. Ungar. / GPL-2	noarch
r-vifcp	1.2	Contains a function to support the following paper: Xiaoping Shi, Xiang-Sheng Wang, Dongwei Wei, Yuehua Wu (2016), <DOI:10.1007/s00180-015-0587-5>, A sequential multiple change-point detection procedure via VIF regression, Computational Statistics, 31(2): 671-691. / LGPL-3	linux-64, osx-64, win-64
r-vigor	1.0	Conducts linear regression using variational Bayesian inference, particularly optimized for genome-wide association mapping and whole-genome prediction which use a number of DNA markers as the explanatory variables. Provides seven regression models which select the important variables (i.e., the variables related to response variables) among the given explanatory variables in different ways (i.e., model structures). / MIT	linux-64, osx-64, win-64
r-violinmplot	0.2.1	A lattice violin-plot is overlaid with the arithmetic mean and standard deviation. / GPL-2	noarch
r-viopoints	0.2.1	viopoints draws one dimensional scatter plots with jitter using kernel density estimates in a similar way to violin plots. / GPL-2	noarch
r-vipor	0.4.5	Generate a violin point plot, a combination of a violin/histogram plot and a scatter plot by offsetting points within a category based on their density using quasirandom noise. / GPL-2	noarch
r- viridis	0.5.1	Implementation of the 'viridis' - the default -, 'magma', 'plasma', 'inferno', and 'cividis' color maps for 'R'. 'viridis', 'magma', 'plasma', and 'inferno' are ported from 'matplotlib' < http://matplotlib.org/ >, a popular plotting library for 'python'. 'cividis', was developed by Jamie R. Nuñez and Sean M. Colby. These color maps are designed in such a way that they will analytically be perfectly perceptually-uniform, both in regular form and also when converted to black-and-white. They are also designed to be perceived by readers with the most common form of color blindness (all color maps in this package) and color vision deficiency ('cividis' only). / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-viridislite	0.3.0	Implementation of the 'viridis' - the default -, 'magma', 'plasma', 'inferno', and 'cividis' color maps for 'R'. 'viridis', 'magma', 'plasma', and 'inferno' are ported from 'matplotlib' < http://matplotlib.org/ >, a popular plotting library for 'python'. 'cividis', was developed by Jamie R. Nuñez and Sean M. Colby. These color maps are designed in such a way that they will analytically be perfectly perceptually-uniform, both in regular form and also when converted to black-and-white. They are also designed to be perceived by readers with the most common form of color blindness (all color maps in this package) and color vision deficiency ('cividis' only). This is the 'lite' version of the more complete 'viridis' package that can be found at < https://cran.r-project.org/package=viridis >. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-virustotal	0.2.1	Use VirusTotal, a Google service that analyzes files and URLs for viruses, worms, trojans etc., provides category of the content hosted by a domain from a variety of prominent services, provides passive DNS information, among other things. See < http://www.virustotal.com > for more information. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-visielse	1.2.1	A graphical tool designed to visualize and to give an overview of behavioral observations realized on individuals or groups. Visualization of raw data during experimental observations of the realization of a procedure. It graphically presents an overview of individuals and group actions usually acquired from timestamps during video recorded sessions. Options of the package allow adding graphical information as statistical indicators (mean, standard deviation, quantile or statistical test) but also for each action green or black zones providing visual information about the accuracy of the realized actions. / AGPL-3	noarch
r-visnetwork	2.0.6	Provides an R interface to the 'vis.js' JavaScript charting library. It allows an interactive visualization of networks. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-visreg	2.5.1	Provides a convenient interface for constructing plots to visualize the fit of regression models arising from a wide variety of models in R ('lm', 'glm', 'coxph', 'rlm', 'gam', 'locfit', 'lmer', 'randomForest', etc.) / GPL-3	noarch
r-visualize	4.3.0	Graphs the pdf or pmf and highlights what area or probability is present in user defined locations. Visualize is able to provide lower tail, bounded, upper tail, and two tail calculations. Supports strict and equal to inequalities. Also provided on the graph is the mean and variance of the distribution. / MIT	noarch
r-vita	1.0.0	Implements the novel testing approach by Janitza et al.(2015) < http://nbn-resolving.de/urn/resolver.pl?urn=nbn:de:bvb:19-epub-25587-4 > for the permutation variable importance measure in a random forest and the PIMP-algorithm by Altmann et al.(2010) <doi:10.1093/bioinformatics/btq134>. Janitza et al.(2015) < http://nbn-resolving.de/urn/resolver.pl?urn=nbn:de:bvb:19-epub-25587-4 > do not use the standard permutation variable importance but the cross-validated permutation variable importance for the novel test approach. The cross-validated permutation variable importance is not based on the out-of-bag observations but uses a similar strategy which is inspired by the cross-validation procedure. The novel test approach can be applied for classification trees as well as for regression trees. However, the use of the novel testing approach has not been tested for regression trees so far, so this routine is meant for the expert user only and its current state is rather experimental. / GPL-2	linux-64, osx-64, win-64
r-vitality	1.3	Provides fitting routines for four versions of the Vitality family of mortality models. / GPL-2	noarch
r-vkr	0.1	Provides an interface to the VK API < https://vk.com/dev/methods >. VK < https://vk.com/ > is the largest European online social networking service, based in Russia. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vlad	0.2.0	Contains functions to set up risk-adjusted quality control charts in health care. For the variable life adjusted display (VLAD) proposed by Lovegrove et al. (1997) <doi:10.1016/S0140-6736(97)06507-0> signaling rules derived in Wittenberg et al. (2018) <doi: 10.1002/sim.7647> are implemented. Additionally, for the risk-adjusted cumulative sum chart based on log-likelihood ratio statistic introduced by Steiner et al. (2000) <doi:10.1093/biostatistics/1.4.441> average run length and control limits can be computed. / GPL-2	linux-64, osx-64, win-64
r-vlf	1.0	Using frequency matrices, very low frequency variants (VLFs) are assessed for amino acid and nucleotide sequences. The VLFs are then compared to see if they occur in only one member of a species, singleton VLFs, or if they occur in multiple members of a species, shared VLFs. The amino acid and nucleotide VLFs are then compared to see if they are concordant with one another. Amino acid VLFs are also assessed to determine if they lead to a change in amino acid residue type, and potential changes to protein structures. / GPL-3	noarch
r-vlmc	1.4.3	Functions, Classes & Methods for estimation, prediction, and simulation (bootstrap) of Variable Length Markov Chain ('VLMC') Models. / GPL-2	linux-64, osx-64, win-64
r-vmask	1.0	The cumulative sum (CUSUM) control chart is considered to be an alternative or complementary to Shewhart control charts in statistical process control (SPC) applications, owing to its higher sensitivity to small shifts in the process mean. It utilizes all the available data rather than the last few ones used in Shewhart control charts for quick decision making. V-mask is a traditional technique for separating meaningful data from unusual circumstances in a Cumulative Sum (CUSUM) control chart; for see details about v-mask see Montgomery (1985, ISBN:978-0471656319). The mask is a V-shaped overlay placed on the CUSUM chart so that one arm of the V lines up with the slope of data points, making it easy to see data points that lie outside the slope and to determine whether these points should be discarded as random events, or treated as a performance trend that should be addressed. But, complex computations is one disadvantage V-mask method for detect small changes in mean using CUSUM control chart. Package 'vMask' can help to the applied users to overcome this challenge by considering six different methods which each of them are based on different information. / LGPL-3	noarch
r-vnm	7.1	Provide tools for finding multiple-objective optimal designs for estimating the shape of dose-response, the ED50 (the dose producing an effect midway between the expected responses at the extreme doses) and the MED (the minimum effective dose level) for the 2,3,4-parameter logistic models and for evaluating its efficiencies for the three objectives. The acronym VNM stands for V-algorithm using Newton Raphson method to search multiple-objective optimal design. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vocaldia	0.8.2	Create adjacency matrices of vocalisation graphs from dataframes containing sequences of speech and silence intervals, transforming these matrices into Markov diagrams, and generating datasets for classification of these diagrams by ‘flattening’ them and adding global properties (functionals) etc. Vocalisation diagrams date back to early work in psychiatry (Jaffe and Feldstein, 1970) and social psychology (Dabbs and Ruback, 1987) but have only recently been employed as a data representation method for machine learning tasks including meeting segmentation (Luz, 2012) <doi:10.1145/2328967.2328970> and classification (Luz, 2013) <doi:10.1145/2522848.2533788>. / GPL-3	noarch
r-volesti	1.0.3	Provides an R interface for ‘volesti’ C package. ‘volesti’ computes estimations of volume of polytopes given by a set of points or linear inequalities or Minkowski sum of segments (zonotopes). There are two algorithms for volume estimation (I.Z. Emiris and V. Fisikopoulos (2014) <arXiv:1312.2873> and B. Cousins, S. Vempala (2016) <arXiv:1409.6011>) as well as algorithms for sampling, rounding and rotating polytopes. Moreover, ‘volesti’ provides algorithms for estimating copulas (L. Cales, A. Chalkis, I.Z. Emiris, V. Fisikopoulos (2018) <arXiv:1803.05861>). / LGPL-3	linux-64, osx-64, win-64
r-volleystat	0.2.0	Volleyball match statistics of the German volleyball first division league (seasons 2013/2014 to 2018/2019). The data has been collected from the official volleyball first division homepage (<www.volleyball-bundesliga.de>) and contains information on teams, staff, sets, matches, and player-in-match statistics (extracted automatically from the official match reports). / CC0	noarch
r-vortexrdata	1.0.5	Contains selected data from two publications, Campbell ‘et’ ‘al’. (2016) <DOI:10.1080/14486563.2015.1028486> and ‘Pacioni’ ‘et’ ‘al’. (2017) <DOI:10.1071/PC17002>. The data is provided both as raw outputs from the population viability analysis software ‘Vortex’ and packaged as R objects. The R package ‘vortexR’ uses the raw data provided here to illustrate its functionality of parsing raw ‘Vortex’ output into R objects. / GPL-3	noarch
r-vote	1.1_0	Counting election votes and determining election results by different methods, including the single transferable vote, approval, score and plurality methods. / GPL-2	noarch
r-votesys	0.1.1	Various methods to count ballots in voting systems are provided. Functions to check validity of ballots are also provided to ensure flexibility. / GPL-3	noarch
r-votrans	1.0	Calculates voter transitions comparing two elections, using the function solve.QP() in package ‘quadprog’. / GPL-3	noarch
r-vowels	1.2_2	Procedures for the manipulation, normalization, and plotting of phonetic and sociophonetic vowel formant data. vowels is the backend for the NORM website. / GPL-3	noarch
r-voxr	0.5.1	Tools for tree crown structure description based on T-LiDAR data voxelisation / GPL (>= 2.0)	noarch
r-vrmlgen	1.4.9	vrmlgen creates 3D scatter and bar plots, visualizations of 3D meshes, parametric functions and height maps in web-formats like the Virtual Reality Markup Language (VRML, filetype .wrl) and the LiveGraphics3D format. / GPL-2	noarch
r-vrtest	0.97	A collection of statistical tests for martingale difference hypothesis / GPL-2	noarch
r-vstsr	1.0.0	Implementation of Visual Studio Team Services < https://www.visualstudio.com/team-services/ > API calls. It enables the extraction of information about repositories, build and release definitions and individual releases. It also helps create repositories and work items within a project without logging into Visual Studio. There is the ability to use any API service with a shell for any non-predefined call. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-vudc	1.1	Contains functions for visualization univariate data: <code>ccdplot</code> and <code>qddplot</code> . / GPL-2	noarch
r-vwr	0.3.0	Functions and data for use in visual word recognition research: Computation of neighbors (Hamming and Levenshtein distances), average distances to neighbors (e.g., OLD20), and Coltheart's N. Also includes the LD1NN algorithm to detect bias in the composition of a lexical decision task. Most of the functions support parallel execution. Supplies wordlists for several languages. Uses the string distance functions from the <code>stringdist</code> package by Mark van der Loo. / GPL-3	noarch
r-w3cmarkupvalidator	0.1_6	R interface to a W3C Markup Validation service. See < http://validator.w3.org/ > for more information. / GPL-2	noarch
r-waffect	1.2	<code>waffect</code> (pronounced 'double-u affect' for 'weighted affectation') is a package to simulate phenotypic (case or control) datasets under a disease model H1 such that the total number of cases is constant across all the simulations (the constrain in the title). The package also makes it possible to generate phenotypes in the case of more than two classes, so that the number of phenotypes belonging to each class is constant across all the simulations. <code>waffect</code> is used to assess empirically the statistical power of Genome Wide Association studies. / GPL-3	linux-64, osx-64, win-64
r-wahc	1.0	Fit the fixed effect panel data model with heteroskedasticity and autocorrelation correction. / GPL-3	noarch
r-waiter	0.0.1	Full screen splash loading screens for 'Shiny'. / MIT	noarch
r-walkscoreapi	1.2	A collection of functions to perform the Application Programming Interface (API) calls associated with the Walk Score website (www.walkscore.com) within the R environment. These functions can be used to query the Walk Score and Transit Score database for a wide variety of information using R scripts. This package includes the simple Walk Score and Transit Score API calls, which return the scores associated with an input location, as well as calls which return some data used to calculate the scores. These functions are especially useful for mass data collection and gathering Walk Score and Transit Score values for large lists of locations. / GPL-2	noarch
r-wamasim	1.0.0	The outcome of various rehabilitation strategies for water distribution systems can be modeled with the Water Management Simulator (WaMaSim). Pipe breaks and the corresponding damage and rehabilitation costs are simulated. It is mainly intended to be used as educational tool for the Water Infrastructure Experimental and Computer Laboratory at ETH Zurich, Switzerland. / GPL-3	noarch
r-wand	0.5.0	'MIME' types are shorthand descriptors for file contents and can be determined from magic bytes in file headers, file contents or intuited from file extensions. Tools are provided to perform curated magic tests as well as mapping 'MIME' types from a database of over 1,500 extension mappings. / MIT	noarch
r-warn	1.2_3	This estimates precise weaning ages for a given skeletal population by analyzing the stable nitrogen isotope ratios of them. Bone collagen turnover rates estimated anew and the approximate Bayesian computation (ABC) were adopted in this package. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-washdata	0.1.2	Urban water and sanitation survey dataset collected by Water and Sanitation for the Urban Poor (WSUP) with technical support from Valid International. These citywide surveys have been collecting data allowing water and sanitation service levels across the entire city to be characterised, while also allowing more detailed data to be collected in areas of the city of particular interest. These surveys are intended to generate useful information for others working in the water and sanitation sector. Current release version includes datasets collected from a survey conducted in Dhaka, Bangladesh in March 2017. This survey in Dhaka is one of a series of surveys to be conducted by WSUP in various cities in which they operate including Accra, Ghana; Nakuru, Kenya; Antananarivo, Madagascar; Maputo, Mozambique; and, Lusaka, Zambia. This package will be updated once the surveys in other cities are completed and datasets have been made available. / CC0	noarch
r-washer	0.1.2	Time series outlier detection by mean of non parametric test. Outlier detection regarding two methodologies: single time series variability (a vector) and grouped similar time series (a data frame). Andrea Venturini(2011) Statistica-Universita' Bologna, Vol.71, pp.329-344. / GPL-2	noarch
r-waterfall	1.0.2	Provides support for creating waterfall charts in R using both traditional base and lattice graphics. / BSD_2_clause	noarch
r-wateryear	1.0.1	Provides Water Year Hydrologic Classification Indices based on measured unimpaired runoff (in million acre-feet). Data is provided by California Department of Water Resources and subject to revision. / MIT	noarch
r-waved	1.2	Makes available code necessary to reproduce figures and tables in papers on the WaveD method for wavelet deconvolution of noisy signals as presented in The WaveD Transform in R, Journal of Statistical Software Volume 21, No. 3, 2007. / GPL-3	noarch
r-wavefunction	1.0.0	Real probability distributions can be represented as the square of an orthogonal sum in the Hermite basis. This representation is formally similar to the representation of quantum mechanical states as wave functions, whose squared modulus is a probability density. This is described in more detail in Wave function representation of probability distributions, by Madeleine B. Thompson <arXiv:1712.07764>. This package provides a reference implementation of the technique. / Apache License (== 2.0)	noarch
r-waveletcomp	1.1	Wavelet analysis and reconstruction of time series, cross-wavelets and phase-difference (with filtering options), significance with simulation algorithms. / GPL-2	noarch
r-wavelets	0.3_0	Contains functions for computing and plotting discrete wavelet transforms (DWT) and maximal overlap discrete wavelet transforms (MODWT), as well as their inverses. Additionally, it contains functionality for computing and plotting wavelet transform filters that are used in the above decompositions as well as multiresolution analyses. / GPL-2	linux-64, osx-64, win-64
r-waveslim	1.7.5	Basic wavelet routines for time series (1D), image (2D) and array (3D) analysis. The code provided here is based on wavelet methodology developed in Percival and Walden (2000); Gencay, Selcuk and Whitcher (2001); the dual-tree complex wavelet transform (DTCWT) from Kingsbury (1999, 2001) as implemented by Selesnick; and Hilbert wavelet pairs (Selesnick 2001, 2002). All figures in chapters 4-7 of GSW (2001) are reproducible using this package and R code available at the book website(s) below. / BSD_3_clause	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wavethresh	4.6.8	Performs 1, 2 and 3D real and complex-valued wavelet transforms, nondecimated transforms, wavelet packet transforms, nondecimated wavelet packet transforms, multiple wavelet transforms, complex-valued wavelet transforms, wavelet shrinkage for various kinds of data, locally stationary wavelet time series, nonstationary multiscale transfer function modeling, density estimation. / GPL-2	linux-64, osx-64, win-64
r-wbs	1.4	Provides efficient implementation of the Wild Binary Segmentation and Binary Segmentation algorithms for estimation of the number and locations of multiple change-points in the piecewise constant function plus Gaussian noise model. / GPL-2	linux-64, osx-64, win-64
r-wce	1.0.2	A flexible method for modeling cumulative effects of time-varying exposures, weighted according to their relative proximity in time, and represented by time-dependent covariates. The current implementation estimates the weight function in the Cox proportional hazards model. The function that assigns weights to doses taken in the past is estimated using cubic regression splines. / GPL-2	noarch
r-wcorr	1.9.1	Calculates Pearson, Spearman, polychoric, and polyserial correlation coefficients, in weighted or unweighted form. The package implements tetrachoric correlation as a special case of the polychoric and biserial correlation as a specific case of the polyserial. / GPL-2	linux-64, osx-64, win-64
r-wcq	0.2	The package contains the WCQ method for detection of QTL effects in a small mapping population. It also contains implementation of the Chen-Qin two-sample and one-sample test of means. / GPL-3	noarch
r-wdi	2.6.0	Search, extract and format data from the World Bank's World Development Indicators. / GPL-3	noarch
r-wdm	0.2.1	Provides efficient implementations of weighted dependence measures and related asymptotic tests for independence. Implemented measures are the Pearson correlation, Spearman's rho, Kendall's tau, Blomqvist's beta, and Hoeffding's D; see, e.g., Nelsen (2006) <doi:10.1007/0-387-28678-0> and Hollander et al. (2015, ISBN:9780470387375). / MIT	linux-64, osx-64, win-64
r-weatherdata	0.5.0	Functions that help in fetching weather data from websites. Given a location and a date range, these functions help fetch weather data (temperature, pressure etc.) for any weather related analysis. / GPL	linux-32, linux-64, osx-64, win-32, win-64
r-weathermetrics	1.2.2	Functions to convert between weather metrics, including conversions for metrics of temperature, air moisture, wind speed, and precipitation. This package also includes functions to calculate the heat index from air temperature and air moisture. / GPL-2	noarch
r-webchem	0.4.0	Chemical information from around the web. This package interacts with a suite of web APIs for chemical information. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-webddx	0.1.0	Freely available online differential-diagnosis generating tools are changing clinical medicine and biomedical research. With webddx, useRs can generate differential diagnosis lists given a set of symptoms. The web tools would likely be directly used in clinical practice, but programmatic interaction and data manipulation can sharply increase efficiency and reproducibility of research in clinical informatics. Relevant visualizations can also be created with webddx. / GPL-3	noarch
r-webex	0.9.1	Functions for easily creating interactive web pages using ‘R Markdown’ that students can use in self-guided learning. / CC BY-SA 4.0	noarch
r-webp	1.0	Lossless webp images are 26% smaller in size compared to PNG. Lossy webp images are 25-34% smaller in size compared to JPEG. This package reads and writes webp images into a 3 (rgb) or 4 (rgba) channel bitmap array using conventions from the ‘jpeg’ and ‘png’ packages. / MIT	linux-64, osx-64, win-64
r-websearchr	0.0.3	Functions that allow for accessing domains and a number of search engines. / MIT	noarch
r-webshot	0.5.1	Takes screenshots of web pages, including Shiny applications and R Markdown documents. / GPL-2	linux-64, noarch, osx-64, win-32, win-64
r-websocket	1.1.0	Provides a ‘WebSocket’ client interface for R. ‘WebSocket’ is a protocol for low-overhead real-time communication: https://en.wikipedia.org/wiki/WebSocket . / GPL-2	linux-64, osx-64, win-64
r-webutils	1.0	Parses http request data in application/json, multipart/form-data, or application/x-www-form-urlencoded format. Includes example of hosting and parsing html form data in R using either ‘httpuv’ or ‘Rhttpd’. / MIT	linux-64, osx-64, win-64
r-weco	1.2	Western Electric Company Rules (WECO) have been widely used for Shewhart control charts in order to increase the sensitivity of detecting assignable causes of process change. This package implements eight commonly used WECO rules and allow to apply the combination of these individual rules for detecting the deviation from a stable process. The package also provides a web-based graphical user interface to help users conduct the analysis. / GPL-3	linux-64, osx-64, win-64
r-wee	1.0	Secondary analysis of case-control studies using a weighted estimating equation (WEE) approach: logistic regression for binary secondary outcomes, linear regression and quantile regression for continuous secondary outcomes. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-weibullness	1.19.8	Performs a goodness-of-fit test of Weibull distribution (weibullness test) and provides the maximum likelihood estimates of the three-parameter Weibull distribution. Note that the threshold parameter is estimated based on the correlation from the Weibull plot. For more details, see Park (2018) <doi:10.1155/2018/6056975>. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (No. NRF-2017R1A2B4004169). / GPL-2 GPL-3	noarch
r-weibullr	1.0.10	Life data analysis in the graphical tradition of Waloddi Weibull. Methods derived from Robert B. Abernethy (2008, ISBN 0-965306-3-2), Wayne Nelson (1982, ISBN: 9780471094586) <DOI:10.1002/0471725234>, William Q. Meeker and Lois A. Escobar (1998, ISBN: 1-471-14328-6), John I. McCool, (2012, ISBN: 9781118217986) <DOI:10.1002/9781118351994>. / GPL-3	linux-64, osx-64, win-64
r-weighted.desc.stat	1.0	Weighted descriptive statistics is the discipline of quantitatively describing the main features of real-valued fuzzy data which usually given from a fuzzy population. One can summarize this special kind of fuzzy data numerically or graphically using this package. To interpret some of the properties of one or several sets of real-valued fuzzy data, numerically summarize is possible by some weighted statistics which are designed in this package such as mean, variance, covariance and correlation coefficient. Also, graphically interpretation can be given by weighted histogram and weighted scatter plot using this package to describe properties of real-valued fuzzy data set. / LGPL-3	noarch
r-weightedporttest	1.0	This packages contains the Weighted Portmanteau Tests as described in New Weighted Portmanteau Statistics for Time Series Goodness-of-Fit Testing' accepted for publication by the Journal of the American Statistical Association. / GPL-3	noarch
r-weightedroc	2018.1	Fast computation of Receiver Operating Characteristic (ROC) curves and Area Under the Curve (AUC) for weighted binary classification problems (weights are example-specific cost values). / GPL-3	noarch
r-weightquant	1.0	Estimation of observation-specific weights for incomplete longitudinal data and bootstrap procedure for weighted quantile regressions. / GPL (>= 2.0)	noarch
r-weirs	0.25	Provides computational support for flow over weirs, such as sharp-crested, broad-crested, and embankments. Initially, the package supports broad- and sharp-crested weirs. / GPL-2	noarch
r-welchadf	0.3.2	Implementation of Johansen's general formulation of Welch-James's statistic with Approximate Degrees of Freedom, which makes it suitable for testing any linear hypothesis concerning cell means in univariate and multivariate mixed model designs when the data pose non-normality and non-homogeneous variance. Some improvements, namely trimmed means and Winsorized variances, and bootstrapping for calculating an empirical critical value, have been added to the classical formulation. The code departs from a previous SAS implementation by L.M. Lix and H.J. Keselman, available at < http://supp.apa.org/psycarticles/supplemental/met_13_2_110/SAS_Program.pdf > and published in Keselman, H.J., Wilcox, R.R., and Lix, L.M. (2003) <DOI:10.1111/1469-8986.00060>. / LGPL-3	noarch
r-wesanderson	0.3.6	Palettes generated mostly from 'Wes Anderson' movies. / MIT	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wfe	1.9.1	Provides a computationally efficient way of fitting weighted linear fixed effects estimators for causal inference with various weighting schemes. Weighted linear fixed effects estimators can be used to estimate the average treatment effects under different identification strategies. This includes stratified randomized experiments, matching and stratification for observational studies, first differencing, and difference-in-differences. The package implements methods described in Imai and Kim (2017) When should We Use Linear Fixed Effects Regression Models for Causal Inference with Longitudinal Data?, available at < https://imai.fas.harvard.edu/research/FEmatch.html >. / GPL-2	linux-64, osx-64, win-64
r-wfg	0.1	Implementation of Weighted Fast Greedy algorithm for community detection in networks with mixed types of attributes. / GPL-2	noarch
r-wgteff	0.1.2	Functions for determining the effect of data weights on the variance of survey data: users will load a data set which has a weights column, and the package will calculate the design effect (DEFF), weighting loss, root design effect (DEFT), effective sample size (ESS), and/or weighted margin of error. / GPL-2	noarch
r-wheatmap	0.1.0	Builds complex plots, heatmaps in particular, using natural semantics. Bigger plots can be assembled using directives such as 'LeftOf', 'RightOf', 'TopOf', and 'Beneath' and more. Other features include clustering, dendrograms and integration with 'ggplot2' generated grid objects. This package is particularly designed for bioinformaticians to assemble complex plots for publication. / GPL-3	noarch
r-whereami	0.1.8	Robust and reliable functions to return informative outputs to console with the run or source location of a command. This can be from the 'RScript'/R terminal commands or 'RStudio' console, source editor, 'Rmarkdown' document and a Shiny application. / MIT	noarch
r-whiboclustering	0.1.2	White Box Cluster Algorithm Design allows you to create Representative based cluster algorithm by using reusable components. This way one can recreate already available cluster algorithms (i.e. K-Means, K-Means, PAM) but also create new cluster algorithms not available in the literature or any other software. For more information see papers <doi:10.1007/s10462-009-9133-6> and <doi:10.1016/j.datak.2012.03.005>. / GPL-3	noarch
r-whisker	0.3.2	logicless templating, reuse templates in many programming languages including R / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-whitechapelr	0.3.0	Provides a set of functions to make tracking the hidden movements of the 'Jack' player easier. By tracking every possible path Jack might have traveled from the point of the initial murder including special movement such as through alleyways and via carriages, the police can more accurately narrow the field of their search. Additionally, by tracking all possible hideouts from round to round, rounds 3 and 4 should have a vastly reduced field of search. / MIT	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-whitening	1.1.1	Implements the whitening methods (ZCA, PCA, Cholesky, ZCA-cor, and PCA-cor) discussed in Kessy, Lewin, and Strimmer (2018) Optimal whitening and decorrelation, <doi:10.1080/00031305.2016.1277159>, as well as the whitening approach to canonical correlation analysis allowing negative canonical correlations described in Jendoubi and Strimmer (2019) A whitening approach to probabilistic canonical correlation analysis for omics data integration, <doi:10.1186/s12859-018-2572-9>. / GPL-3	noarch
r-whoami	1.3.0	Look up the username and full name of the current user, the current user's email address and 'GitHub' username, using various sources of system and configuration information. / MIT	noarch
r-whoapi	0.1.2	Retrieve data from the 'Whoapi' (https://whoapi.com) store of domain information, including a domain's geographic location, registration status and search prominence. / MIT	noarch
r-whopgenome	0.9.7	Provides very fast access to whole genome, population scale variation data from VCF files and sequence data from FASTA-formatted files. It also reads in alignments from FASTA, Phylip, MAF and other file formats. Provides easy-to-use interfaces to genome annotation from UCSC and Bioconductor and gene ontology data from AmiGO and is capable to read, modify and write PLINK .PED-format pedigree files. / GPL-2	linux-64, osx-64, win-64
r-wicket	0.4.0	Utilities to generate bounding boxes from 'WKT' (Well-Known Text) objects and R data types, validate 'WKT' objects and convert object types from the 'sp' package into 'WKT' representations. / MIT	linux-64, osx-64, win-64
r-widgetframe	0.3.1	Provides two functions 'frameableWidget()', and 'frameWidget()'. The 'frameableWidget()' is used to add extra code to a 'htmlwidget' which allows is to be rendered correctly inside a responsive 'iframe'. The 'frameWidget()' is a 'htmlwidget' which displays content of another 'htmlwidget' inside a responsive 'iframe'. These functions allow for easier embedding of 'htmlwidgets' in content management systems such as 'wordpress', 'blogger' etc. They also allow for separation of widget content from main HTML content where CSS of the main HTML could interfere with the widget. / MIT	noarch
r-wikibooks	0.2	The german Wikibook GNU R introduces R to new users. This package is a collection of functions and datas used in the german WikiBook GNU R / GPL-2	noarch
r-wikifacts	0.1.0	Creates messages containing random facts from the Wikipedia homepage. Intended to keep users interested during long waiting periods. / CC0	noarch
r-wikipediarr	1.1	Provides an interface to the Wikipedia web application programming interface (API), using internet connexion. Three functions provide details for a specific Wikipedia page : all links that are present, all pages that link to, all the contributions (revisions for main pages, and discussions for talk pages). Two functions provide details for a specific user : all contributions, and general information (as name, gender, rights or groups). It provides additional information compared to others packages, as WikipediR. It does not need login. The multiplex network that can be constructed from the results of the functions of Wikipediarr can be modeled as Stochastic Block Model as in Barbillon P., Donnet, S., Lazega E., and Bar-Hen A. : Stochastic Block Models for Multiplex networks: an application to networks of researchers, ArXiv 1501.06444, http://arxiv.org/abs/1501.06444 . / GPL (> 2)	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wikipedir	1.5.0	A wrapper for the MediaWiki API, aimed particularly at the Wikimedia ‘production’ wikis, such as Wikipedia. It can be used to retrieve page text, information about users or the history of pages, and elements of the category tree. / MIT	noarch
r-wilcoxcv	1.0_2	This package provides functions to perform fast variable selection based on the Wilcoxon rank sum test in the cross-validation or Monte-Carlo cross-validation settings, for use in microarray-based binary classification. / GPL-2	noarch
r-wildcard	1.1.0	Generate data frames from templates. / GPL-3	noarch
r-wildpoker	1.1	Provides insight into how the best hand for a poker game changes based on the game dealt, players who stay in until the showdown and wildcards added to the base game. At this time the package does not support player tactics, so draw poker variants are not included. / GPL-3	noarch
r-wingui	0.2	Helps for interfacing with the operating system particularly for Windows. / GPL-2 GPL-3 MIT	linux-64, osx-64, win-64
r-wisam	0.2.8	In the course of a genome-wide association study, the situation often arises that some phenotypes are known with greater precision than others. It could be that some individuals are known to harbor more micro-environmental variance than others. In the case of inbred strains of model organisms, it could be the case that more organisms were observed from some strains than others, so the strains with more organisms have better-estimated means. Package ‘wISAM’ handles this situation by allowing for weighting of each observation according to residual variance. Specifically, the ‘weight’ parameter to the function conduct_scan() takes the precision of each observation (one over the variance). / GPL-3	noarch
r-withr	2.1.2	A set of functions to run code ‘with’ safely and temporarily modified global state. Many of these functions were originally a part of the ‘devtools’ package, this provides a simple package with limited dependencies to provide access to these functions. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-wkb	0.3_0	Utility functions to convert between the ‘Spatial’ classes specified by the package ‘sp’, and the well-known binary ‘(WKB)’ representation for geometry specified by the Open Geospatial Consortium. Supports ‘Spatial’ objects of class ‘SpatialPoints’, ‘SpatialPointsDataFrame’, ‘SpatialLines’, ‘SpatialLinesDataFrame’, ‘SpatialPolygons’, and ‘SpatialPolygonsDataFrame’. Supports ‘WKB’ geometry types ‘Point’, ‘LineString’, ‘Polygon’, ‘MultiPoint’, ‘MultiLineString’, and ‘MultiPolygon’. Includes extensions to enable creation of maps with ‘TIBCO Spotfire’. / BSD_3_clause	noarch
r-wktmo	1.0.5	Converts weekly data to monthly data. Users can use three types of week formats: ISO week, epidemiology week (epi week) and calendar date. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wlreg	1.0.0	Use various regression models for the analysis of win loss endpoints adjusting for non-binary and multivariate covariates. / GPL-2	linux-64, osx-64, win-64
r-wmdb	1.0	Distance discriminant analysis method is one of classification methods according to multiindex performance parameters. However, the traditional Mahalanobis distance discriminant method treats with the importance of all parameters equally, and exaggerates the role of parameters which changes a little. The weighted Mahalanobis distance is used in discriminant analysis method to distinguish the importance of each parameter. In the concrete application, firstly based on the principal component analysis scheme, a new group of parameters and their corresponding percent contributions of the parameters are calculated, and the weighted matrix is regarded as the diagonal matrix of the contributions rates. Setting data to standardization, then the weighted Mahalanobis distance can be calculated. Besides the methods mentioned above, bayes method is also given. / GPL-2	noarch
r-wmwssp	0.4.0	Calculates the minimal sample size for the Wilcoxon-Mann-Whitney test that is needed for a given power and two sided type I error rate. The method works for metric data with and without ties, count data, ordered categorical data, and even dichotomous data. But data is needed for the reference group to generate synthetic data for the treatment group based on a relevant effect. For details, see Brunner, E., Bathke A. C. and Konietzschke, F: Rank- and Pseudo-Rank Procedures in Factorial Designs - Using R and SAS, Springer Verlag, to appear. / GPL-3	noarch
r-wnl	0.5.1	This is a set of minimization tools (maximum likelihood estimation and least square fitting) to solve examples in the Johan Gabrielsson and Dan Weiner's book Pharmacokinetic and Pharmacodynamic Data Analysis - Concepts and Applications 5th ed. (ISBN:9198299107). Examples include linear and non-linear compartmental model, turn-over model, single or multiple dosing bolus/infusion/oral models, allometry, toxicokinetics, reversible metabolism, in-vitro/in-vivo extrapolation, enterohepatic circulation, metabolite modeling, Emax model, inhibitory model, tolerance model, oscillating response model, enantiomer interaction model, effect compartment model, drug-drug interaction model, receptor occupancy model, and rebound phenomena model. / GPL-3	noarch
r-wnnsel	0.1	New tools for the imputation of missing values in high-dimensional data are introduced using the non-parametric nearest neighbor methods. It includes weighted nearest neighbor imputation methods that use specific distances for selected variables. It includes an automatic procedure of cross validation and does not require prespecified values of the tuning parameters. It can be used to impute missing values in high-dimensional data when the sample size is smaller than the number of predictors. For more information see Faisal and Tutz (2017) <doi:10.1515/sagmb-2015-0098>. / GPL-2	noarch
r-woe	0.2	Shows the relationship between an independent and dependent variable through Weight of Evidence and Information Value. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-woebinning</code>	0.1.6	Implements an automated binning of numeric variables and factors with respect to a dichotomous target variable. Two approaches are provided: An implementation of fine and coarse classing that merges granular classes and levels step by step. And a tree-like approach that iteratively segments the initial bins via binary splits. Both procedures merge, respectively split, bins based on similar weight of evidence (WOE) values and stop via an information value (IV) based criteria. The package can be used with single variables or an entire data frame. It provides flexible tools for exploring different binning solutions and for deploying them to (new) data. / GPL-2	noarch
<code>r-wooldridge</code>	1.3.1	Students learning both econometrics and R may find the introduction to both challenging. However, if the text is Introductory Econometrics: A Modern Approach by Jeffrey M. Wooldridge, they are in luck! The wooldridge data package aims to lighten the task by efficiently loading any data set found in the text with a single command. Data sets have all been compressed to a fraction of their original size and are well documented. Documentation files contain the page numbers of the text where each set is used, the original source, time of publication, and notes suggesting ideas for further exploratory data analysis and research. If one need's to brush-up on model syntax, a vignette contains R solutions to examples from each chapter of the text. Data sets are from the 6th edition (Wooldridge 2016, ISBN-13: 978-1-305-27010-7), and are backwards compatible with all versions of the text. / GPL-3	noarch
<code>r-word.alignment</code>	1.1	For a given Sentence-Aligned Parallel Corpus, it aligns words for each sentence pair. It considers one-to-many and symmetrization alignments. Moreover, it evaluates the quality of word alignment based on this package and some other software. It also builds an automatic dictionary of two languages based on given parallel corpus. / GPL-2	noarch
<code>r-wordcloud</code>	2.6	Functionality to create pretty word clouds, visualize differences and similarity between documents, and avoid over-plotting in scatter plots with text. / LGPL-2.1	linux-64, osx-64, win-64
<code>r-wordcloud2</code>	0.2.1	A fast visualization tool for creating wordcloud by using 'wordcloud2.js'. 'wordcloud2.js' is a JavaScript library to create wordle presentation on 2D canvas or HTML < https://timdream.org/wordcloud2.js/ >. / GPL-2	noarch
<code>r-wordmatch</code>	1.0	Matches words in one file with words in another file and shows index(row number) for the matches / GPL-2	noarch
<code>r-wordnet</code>	0.1.1	An interface to WordNet using the Jawbone Java API to WordNet. WordNet (< http://wordnet.princeton.edu/ >) is a large lexical database of English. Nouns, verbs, adjectives and adverbs are grouped into sets of cognitive synonyms (synsets), each expressing a distinct concept. Synsets are interlinked by means of conceptual-semantic and lexical relations. Please note that WordNet(R) is a registered tradename. Princeton University makes WordNet available to research and commercial users free of charge provided the terms of their license (< http://wordnet.princeton.edu/wordnet/license/ >) are followed, and proper reference is made to the project using an appropriate citation (< http://wordnet.princeton.edu/wordnet/citing-wordnet/ >). / MIT	noarch
<code>r-wordpools</code>	1.1.1	Collects several classical word pools used most often to provide lists of words in psychological studies of learning and memory. It provides a simple function, 'pickList' for selecting random samples of words within given ranges. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-worms	0.2.2	Retrieves taxonomic information from http://www.marinespecies.org using WoRMS' RESTful Webservice. Utility functions aim at taxonomic consistency. / AGPL-3	noarch
r-wperm	1.0.1	Supplies permutation-test alternatives to traditional hypothesis-test procedures such as two-sample tests for means, medians, and standard deviations; correlation tests; tests for homogeneity and independence; and more. Suitable for general audiences, including individual and group users, introductory statistics courses, and more advanced statistics courses that desire an introduction to permutation tests. / GPL-2	noarch
r-wpkde	0.1	Weighted Piecewise Kernel Density Estimation for large data. / GPL-3	linux-64, osx-64, win-64
r-wpp2008	1.0_1	Data from the United Nation's World Population Prospects 2008 / GPL-2	noarch
r-wpp2010	1.2_0	Data from the United Nation's World Population Prospects 2010 / GPL-2	noarch
r-wpp2012	2.2_1	Data from the United Nation's World Population Prospects 2012 / GPL-2	noarch
r-wpp2015	1.1_2	Provides data from the United Nation's World Population Prospects 2015. / GPL-2	noarch
r-wpp2017	1.2_1	Provides data from the United Nation's World Population Prospects 2017. / GPL-2	noarch
r-wpp2019	1.0_0	Provides data from the United Nation's World Population Prospects 2019. / file LICENSE	noarch
r-wrapr	1.8.9	Tools for writing and debugging R code. Provides: '%.>%' dot-pipe (an 'S3' configurable pipe), 'let()' (converts non-standard evaluation interfaces to parametric standard evaluation interfaces, inspired by 'gtools:strmacro()' and 'base::bquote()'), 'build_frame()'/draw_frame()' ('data.frame' example tools), 'qc()' (quoting concatenate), ':= ' (named map builder), and more. / GPL-2 GPL-3	noarch
r-wrassp	0.1.8	A wrapper around Michel Scheffers's 'libassp' (http://libassp.sourceforge.net/). The 'libassp' (Advanced Speech Signal Processor) library aims at providing functionality for handling speech signal files in most common audio formats and for performing analyses common in phonetic science/speech science. This includes the calculation of formants, fundamental frequency, root mean square, auto correlation, a variety of spectral analyses, zero crossing rate, filtering etc. This wrapper provides R with a large subset of 'libassp's signal processing functions and provides them to the user in a (hopefully) user-friendly manner. / GPL-3	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wrightmap	1.2.1	A powerful yet simple graphical tool available in the field of psychometrics is the Wright Map (also known as item maps or item-person maps), which presents the location of both respondents and items on the same scale. Wright Maps are commonly used to present the results of dichotomous or polytomous item response models. The ‘WrightMap’ package provides functions to create these plots from item parameters and person estimates stored as R objects. Although the package can be used in conjunction with any software used to estimate the IRT model (e.g. ‘TAM’, ‘mirt’, ‘eRm’ or ‘IRTToys’ in ‘R’, or ‘Stata’, ‘Mplus’, etc.), ‘WrightMap’ features special integration with ‘ConQuest’ to facilitate reading and plotting its output directly. The ‘wrightMap’ function creates Wright Maps based on person estimates and item parameters produced by an item response analysis. The ‘CQmodel’ function reads output files created using ‘ConQuest’ software and creates a set of data frames for easy data manipulation, bundled in a ‘CQmodel’ object. The ‘wrightMap’ function can take a ‘CQmodel’ object as input or it can be used to create Wright Maps directly from data frames of person and item parameters. / BSD_2_clause	noarch
r-write.snns	0.0_4	Function for writing a SNNS pattern file from a data.frame or matrix. / GPL-2	noarch
r-writexl	1.1	Zero-dependency data frame to xlsx exporter based on ‘libxlsxwriter’. Fast and no Java or Excel required. / BSD_2_clause	linux-64, osx-64, win-64
r-writexls	5.0.0	Cross-platform Perl based R function to create Excel 2003 (XLS) and Excel 2007 (XLSX) files from one or more data frames. Each data frame will be written to a separate named worksheet in the Excel spreadsheet. The worksheet name will be the name of the data frame it contains or can be specified by the user. / GPL-2	noarch
r-wrswor	1.1	A collection of implementations of classical and novel algorithms for weighted sampling without replacement. / GPL-3	linux-64, osx-64, win-64
r-wrswor.benchmark	0.2	Includes performance measurements and results of repeated experiment runs (for correctness checks) for code in the ‘wrswor’ package. / GPL-3	noarch
r-wskm	1.4.28	Entropy weighted k-means (ewkm) is a weighted subspace clustering algorithm that is well suited to very high dimensional data. Weights are calculated as the importance of a variable with regard to cluster membership. The two-level variable weighting clustering algorithm tw-k-means (twkm) introduces two types of weights, the weights on individual variables and the weights on variable groups, and they are calculated during the clustering process. The feature group weighted k-means (fgkm) extends this concept by grouping features and weighting the group in addition to weighting individual features. / GPL-3	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-wsrf	1.7.17	A parallel implementation of Weighted Subspace Random Forest. The Weighted Subspace Random Forest algorithm was proposed in the International Journal of Data Warehousing and Mining by Baoxun Xu, Joshua Zhexue Huang, Graham Williams, Qiang Wang, and Yunming Ye (2012) <DOI:10.4018/jdwm.2012040103>. The algorithm can classify very high-dimensional data with random forests built using small subspaces. A novel variable weighting method is used for variable subspace selection in place of the traditional random variable sampling. This new approach is particularly useful in building models from high-dimensional data. / GPL-2	linux-64, osx-64, win-64
r-wsvm	0.1.7	We propose weighted SVM methods with penalization form. By adding weights to loss term, we can build up weighted SVM easily and examine classification algorithm properties under weighted SVM. Through comparing each of test error rates, we conclude that our Weighted SVM with boosting has predominant properties than the standard SVM have, as a whole. / GPL-2	noarch
r-wtest	3.2	Perform the calculation of W-test, diagnostic checking, calculate minor allele frequency (MAF) and odds ratio. / GPL-2	linux-64, osx-64, win-64
r-wtss	1.1.0	An R client that provides remote access to satellite image time series. The client allows Earth observation users to obtain time series from data sets available in a Web Time Series Server. The functions include: (a) listing the data sets available in the server; (b) describing the contents of a data set; (c) retrieving a time series based on spatial location and temporal filters. / GPL-3	noarch
r-wvtool	1.0	This tool, wood vision tool, is intended to facilitate preprocessing and analyzing 2-dimensional wood images toward automated recognition. The former includes some basics such as functions to RGB to grayscale, gray to binary, cropping, rotation(bilinear), median/mean/Gaussian filter, and Canny/Sobel edge detection. The latter includes gray level co-occurrence matrix (GLCM), Haralick parameters, local binary pattern (LBP), higher order local autocorrelation (HLAC), Fourier transform (radial and azimuthal integration), and Gabor filtering. The functions are intended to read data using 'readTIFF(x,info=T)' from 'tiff' package. The functions in this packages basically assumes the grayscale images as input data, thus the color images should be subjected to the function rgb2gray() before used for some other functions. / GPL-2	noarch
r-wwgbook	1.0.1	Book is Linear Mixed Models: A Practical Guide Using Statistical Software published in 2006 by Chapman Hall / CRC Press / GPL-2	noarch
r-wwr	1.2.2	Calculate the (weighted) win loss statistics including the win ratio, win difference and win product and their variances, with which the p-values are also calculated. The variance estimation is based on Luo et al. (2015) <doi:10.1111/biom.12225> and Luo et al. (2017) <doi:10.1002/sim.7284>. This package also calculates general win loss statistics with user-specified win loss function with variance estimation based on Bebu and Lachin (2016) <doi:10.1093/biostatistics/kxv032>. This version corrected an error when outputting confidence interval for win difference. / GPL-2	linux-64, osx-64, win-64
r-x12	1.9.0	The 'X13-ARIMA-SEATS' < https://www.census.gov/srd/www/x13as/ > methodology and software is a widely used software and developed by the US Census Bureau. It can be accessed from 'R' with this package and 'X13-ARIMA-SEATS' binaries are provided by the 'R' package 'x13binary'. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r-x13binary</code>	1.1.39	The US Census Bureau provides a seasonal adjustment program now called ‘X-13ARIMA-SEATS’ building on both earlier programs called X-11 and X-12 as well as the SEATS program by the Bank of Spain. The US Census Bureau offers both source and binary versions – which this package integrates for use by other R packages. / file LICENSE	linux-64, noarch, osx-64, win-32, win-64
<code>r-xbrl</code>	0.99.1	Functions to extract business financial information from an Extensible Business Reporting Language (‘XBRL’) instance file and the associated collection of files that defines its ‘Discoverable’ Taxonomy Set (‘DTS’). / GPL-2	linux-64, osx-64, win-64
<code>r-xfun</code>	0.6	Miscellaneous functions commonly used in other packages maintained by ‘Yihui Xie’. / MIT file LICENSE	linux-64, noarch, osx-64, win-32, win-64
<code>r-xgboost</code>	0.90.0	Extreme Gradient Boosting, which is an efficient implementation of the gradient boosting framework from Chen & Guestrin (2016) <doi:10.1145/2939672.2939785>. This package is its R interface. The package includes efficient linear model solver and tree learning algorithms. The package can automatically do parallel computation on a single machine which could be more than 10 times faster than existing gradient boosting packages. It supports various objective functions, including regression, classification and ranking. The package is made to be extensible, so that users are also allowed to define their own objectives easily. / Apache License (== 2.0) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
<code>r-xgboost-cpu</code>	0.90	None / None	linux-64, osx-64, win-64
<code>r-xgboost-gpu</code>	0.80	None / None	linux-64
<code>r-xgobi</code>	1.2_1	Interface to the XGobi and XGvis programs for graphical data analysis. / file LICENSE	noarch
<code>r-xhwe</code>	1.0	Conduct the likelihood ratio tests for Hardy-Weinberg equilibrium at marker loci on the X chromosome. / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-ximble	0.10.1	Provides a simple XML tree parser/generator. It includes functions to read XML files into R objects, get information out of and into nodes, and write R objects back to XML code. It's not as powerful as the 'XML' package and doesn't aim to be, but for simple XML handling it could be useful. It was originally developed for the R GUI and IDE 'RKWard' < https://rkward.kde.org >, to make plugin development easier. / GPL-3	noarch
r-xlconnectjars	0.2.1	Provides external JAR dependencies for the XLConnect package. / GPL-3	noarch
r-xlink	1.0.1	The expression of X-chromosome undergoes three possible biological processes: X-chromosome inactivation (XCI), escape of the X-chromosome inactivation (XCI-E), and skewed X-chromosome inactivation (XCI-S). To analyze the X-linked genetic association for phenotype such as continuous, binary, and time-to-event outcomes with the actual process unknown, we propose a unified approach of maximizing the likelihood or partial likelihood over all of the potential biological processes. The methods are described in Wei Xu, Meiling Hao (2017) <doi:10.1002/gepi.22097>. And also see Dongxiao Han, Meiling Hao, Lianqiang Qu, Wei Xu (2019) <doi:10.1177/0962280219859037>. / GPL-2	noarch
r-xllim	2.1	Provides a tool for non linear mapping (non linear regression) using a mixture of regression model and an inverse regression strategy. The methods include the GLLiM model (see Deleforge et al (2015) <DOI:10.1007/s11222-014-9461-5>) based on Gaussian mixtures and a robust version of GLLiM, named SLLiM (see Perthame et al (2016) < https://hal.archives-ouvertes.fr/hal-01347455 >) based on a mixture of Generalized Student distributions. The methods also include BLLiM (see Devijver et al (2017) < https://arxiv.org/abs/1701.07899 >) which is an extension of GLLiM with a sparse block diagonal structure for large covariance matrices (particularly interesting for transcriptomic data). / GPL-2	noarch
r-xlsimple	0.0.1	Provides a simple wrapper for some 'XLConnect' functions. 'XLConnect' is a package that allows for reading, writing, and manipulating Microsoft Excel files. This package, 'xlsimple', adds some documentation and pre-defined formatting to the outputted Excel file. Individual sheets can include a description on the first row to remind user what is in the data set. Auto filters and freeze rows are turned on. A brief readme file is created that provides a summary listing of the created sheets and, where provided, the description. / GPL-3	noarch
r-xlsx	0.6.1	Provide R functions to read/write/format Excel 2007 and Excel 97/2000/XP/2003 file formats. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-xlsxjars	0.6.1	The xlsxjars package collects all the external jars required for the xlsx package. This release corresponds to POI 3.10.1. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-xltabr	0.1.2	Writes beautifully formatted cross tabulations to Excel using ‘openxlsx’. It has been developed to help automate the process of publishing Official Statistics. The user provides a dataframe, which is outputted to Excel with various types of rich formatting which are automatically detected from the structure of the cross tabulation. Documentation can be found at the following url < https://github.com/moj-analytical-services/xltabr >. / GPL-3	noarch
r-xmisc	0.2.1	This is Xiaobei’s miscellaneous classes and functions useful when developing R packages, particularly for OOP using R Reference Class. / GPL-2	noarch
r-xml	3.98	Many approaches for both reading and creating XML (and HTML) documents (including DTDs), both local and accessible via HTTP or FTP. Also offers access to an ‘XPath’ interpreter. / BSD_2_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-xml2	1.2.0	Work with XML files using a simple, consistent interface. Built on top of the ‘libxml2’ C library. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-xml2r	0.0.6	XML2R is a framework that reduces the effort required to transform XML content into number of tables while preserving parent to child relationships. / GPL-2	noarch
r-xmlparsedata	1.0.2	Convert the output of ‘utils::getParseData()’ to an ‘XML’ tree, that one can search via ‘XPath’, and easier to manipulate in general. / MIT	noarch
r-xmlrpc2	1.1	The ‘XML-RPC’ is a remote procedure call protocol based on ‘XML’. The ‘xmlrpc2’ package is inspired by the ‘XMLRPC’ package but uses the ‘curl’ and ‘xml2’ packages instead ‘RCurl’ and ‘XML’. / GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-xnomial	1.0.4	Tests whether a set of counts fit a given expected ratio. For example, a genetic cross might be expected to produce four types in the relative frequencies of 9:3:3:1. To see whether a set of observed counts fits this expectation, one can examine all possible outcomes with <code>xmulti()</code> or a random sample of them with <code>xmonte()</code> and find the probability of an observation deviating from the expectation by at least as much as the observed. As a measure of deviation from the expected, one can use the log-likelihood ratio, the multinomial probability, or the classic chi-square statistic. A histogram of the test statistic can also be plotted and compared with the asymptotic curve. / GPL-3	linux-64, osx-64, win-64
r-xopen	1.0.0	Cross platform solution to open files, directories or ‘URLs’ with their associated programs. / MIT file LICENSE	noarch
r-xplorerr	0.1.1	Tools for interactive data exploration built using ‘shiny’. Includes apps for descriptive statistics, visualizing probability distributions, inferential statistics, linear regression, logistic regression and RFM analysis. / MIT	noarch
r-xptr	1.1.1	There is limited native support for external pointers in the R interface. This package provides some basic tools to verify, create and modify ‘externalptr’ objects. / MIT	linux-64, osx-64, win-64
r-xr	0.7.2	Support for interfaces from R to other languages, built around a class for evaluators and a combination of functions, classes and methods for communication. Will be used through a specific language interface package. Described in the book Extending R. / GPL-2	noarch
r-xrscc	0.1	This is a set of statistical quality control functions, that allows plotting control charts and its iterations, process capability for variable and attribute control, highlighting the <code>xrs_gr()</code> function, like a first iteration for variable chart, meanwhile the <code>we_rules()</code> function detects non random patterns in sample. / GPL-2	noarch
r-xslt	1.3	An extension for the ‘xml2’ package to transform XML documents by applying an ‘xslt’ style-sheet. / GPL-2	linux-64, osx-64, win-64
r-xtable	1.8_4	Coerce data to LaTeX and HTML tables. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
r-xtal	1.15	This is the tool set for crystallographer to design and analyze crystallization experiments, especially for ribosome from Mycobacterium tuberculosis. / GPL-2 GPL-3	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-xtensor	0.11.1	The 'xtensor' C library for numerical analysis with multi-dimensional array expressions is provided as a header-only C14 library. It offers an extensible expression system enabling lazy broadcasting; an API following the idioms of the C standard library; and tools to manipulate array expressions and build upon 'xtensor'. / BSD_3_clause	linux-64, osx-64, win-64
r-xtermstyle	3.0.5	Can be used for coloring output in terminals. It was developed for the standard Ubuntu terminal but should be compatible with any terminal using xterm or ANSI escape sequences. If run in windows, RStudio, or any other platform not supporting such escape sequences it gracefully passes on any output without modifying it. / GPL-2	noarch
r-xts	0.11.2	Provide for uniform handling of R's different time-based data classes by extending zoo, maximizing native format information preservation and allowing for user level customization and extension, while simplifying cross-class interoperability. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
r-xwf	0.2.2	Extrema-weighted feature extraction for varying length functional data. Functional data analysis method that performs dimensionality reduction based on predefined features and allows for quantile weighting. Method implemented as presented in Van den Boom et al. (2018) <doi:10.1093/bioinformatics/bty120>. / MIT	noarch
r-xyloplot	1.6	A method for creating vertical histograms sharing a y-axis using base graphics. / GPL-2	noarch
r-xyz	0.2	High dimensional interaction search by brute force requires a quadratic computational cost in the number of variables. The xyz algorithm provably finds strong interactions in almost linear time. For details of the algorithm see: G. Thanei, N. Meinshausen and R. Shah (2016). The xyz algorithm for fast interaction search in high-dimensional data < https://arxiv.org/pdf/1610.05108v1.pdf >. / GPL-3	linux-64, osx-64, win-64
r-yacca	1.1.1	Provides an alternative canonical correlation/redundancy analysis function, with associated print, plot, and summary methods. A method for generating helio plots is also included. / GPL-3	noarch
r-yaimpute	1.0.3	Performs nearest neighbor-based imputation using one or more alternative approaches to processing multivariate data. These include methods based on canonical correlation analysis, canonical correspondence analysis, and a multivariate adaptation of the random forest classification and regression techniques of Leo Breiman and Adele Cutler. Additional methods are also offered. The package includes functions for comparing the results from running alternative techniques, detecting imputation targets that are notably distant from reference observations, detecting and correcting for bias, bootstrapping and building ensemble imputations, and mapping results. / GPL-2	linux-64, osx-64, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-yakmor	0.1.1	This is a simple wrapper for the yakmo K-Means library (developed by Naoki Yoshinaga, see http://www.tkl.iis.u-tokyo.ac.jp/~ynaga/yakmo/). It performs fast and robust (orthogonal) K-Means. / GPL-2	linux-64, osx-64, win-64
r-yaletoolkit	4.2.2	This collection of data exploration tools was developed at Yale University for the graphical exploration of complex multivariate data; barcode and gpairs now have their own packages. The new big.read.table() provided here may be useful for large files when only a subset is needed. / LGPL-3	noarch
r-yaml	2.2.0	Implements the ‘libyaml’ ‘YAML’ 1.1 parser and emitter (< http://pyyaml.org/wiki/LibYAML >) for R. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
r-yarr	0.1.2	A parser and a writer for ‘WEKA’ Attribute-Relation File Format < https://waikato.github.io/weka-wiki/arff_stable/ > in pure R, with no dependencies. As opposed to other R implementations, this package can read standard (dense) as well as sparse files, i.e. those where each row does only contain nonzero components. Unlike ‘RWeka’, ‘yarr’ does not require any ‘Java’ installation nor is dependent on external software. This implementation is generalized from those in packages ‘mldr’ and ‘mldr.datasets’. / GPL-3	noarch
r-yasp	0.2.0	A collection of string functions designed for writing compact and expressive R code. ‘yasp’ (Yet Another String Package) is simple, fast, dependency-free, and written in pure R. The package provides: a coherent set of abbreviations for paste() from package ‘base’ with a variety of defaults, such as p() for paste and pcc() for paste and collapse with commas; wrap(), bracket(), and others for wrapping a string in flanking characters; unwrap() for removing pairs of characters (at any position in a string); and sentence() for cleaning whitespace around punctuation and capitalization appropriate for prose sentences. / MIT	noarch
r-yatah	0.0.1	Provides functions to manage taxonomy when lineages are described with strings and ranks separated with special patterns like *__ or ;*__. / GPL-3	noarch
r-yesno	0.1.0	Asks Yes-No questions with variable or custom responses. / GPL-2	noarch
r-yhatr	0.15.1	Deploy, maintain, and invoke models via the Yhat REST API. / FreeBSD	noarch
r-yieldcurve	4.1	Modelling the yield curve with some parametric models. The models implemented are: Nelson-Siegel, Diebold-Li and Svensson. The package also includes the data of the term structure of interest rate of Federal Reserve Bank and European Central Bank. / GPL-2	noarch
r-ykmeans	1.0	The clustering by k-means of using the target variable. To determine the number of clusters with the variance of the target variable in the cluster. / GPL-3	noarch
r-yll	1.0.0	Compute the standard expected years of life lost (YLL), as developed by the Global Burden of Disease Study (Murray, C.J., Lopez, A.D. and World Health Organization, 1996). The YLL is based on comparing the age of death to an external standard life expectancy curve. It also computes the average YLL, which highlights premature causes of death and brings attention to preventable deaths (Aragon et al., 2008). / GPL-2	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-yonder	0.1.1	Build ‘shiny’ applications with the latest Bootstrap components and design utilities. Includes refreshed reactive inputs and outputs. Use responsive layouts to design and construct applications for devices of all sizes. / GPL-3	noarch
r-ypinterimtesting	1.0.3	For any spending function specified by the user, this package provides corresponding boundaries for interim testing using the adaptively weighted log-rank test developed by Yang and Prentice (2010 <doi:10.1111/j.1541-0420.2009.01243.x>). The package uses a re-sampling method to obtain stopping boundaries at the interim looks. The output consists of stopping boundaries and observed values of the test statistics at the interim looks, along with nominal p-values defined as the probability of the test exceeding the specific observed test statistic value or critical value, regardless of the test behavior at other looks. The asymptotic validity of the stopping boundaries is established in Yang (2018 <doi:10.1002/sim.7958>). / GPL-3	linux-64, osx-64, win-64
r-ypmodel	1.3	Inference procedures accommodate a flexible range of hazard ratio patterns with a two-sample semi-parametric model. This model contains the proportional hazards model and the proportional odds model as sub-models, and accommodates non-proportional hazards situations to the extreme of having crossing hazards and crossing survivor functions. Overall, this package has four major functions: 1) the parameter estimation, namely short-term and long-term hazard ratio parameters; 2) 95 percent and 90 percent point-wise confidence intervals and simultaneous confidence bands for the hazard ratio function; 3) p-value of the adaptive weighted log-rank test; 4) p-values of two lack-of-fit tests for the model. See the included read_me_first.pdf for brief instructions. In this version (1.1), there is no need to sort the data before applying this package. / GPL-3	noarch
r-yum	0.0.1	Provides a number of functions to facilitate extracting information in ‘YAML’ fragments from one or multiple files, optionally structuring the information in a ‘data.tree’. ‘YAML’ (recursive acronym for YAML ain’t Markup Language) is a convention for specifying structured data in a format that is both machine- and human-readable. ‘YAML’ therefore lends itself well for embedding (meta)data in plain text files, such as Markdown files. This principle is implemented in ‘yum’ with minimal dependencies (i.e. only the ‘yaml’ packages, and the ‘data.tree’ package can be used to enable additional functionality). / GPL-3	noarch
r-yummlyr	0.1.1	Yummly.com is one of the world’s largest and most powerful recipe search sites and this package aims to provide R bindings for publicly available Yummly.com Recipe API (https://developer.yummly.com/). / GPL-2	noarch
r-zeallot	0.1.0	Provides a %<-% operator to perform multiple, unpacking, and destructuring assignment in R. The operator unpacks the right-hand side of an assignment into multiple values and assigns these values to variables on the left-hand side of the assignment. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-64
r-zen4r	0.3	Provides an Interface to ‘Zenodo’ (< https://zenodo.org >) REST API, including management of depositions, attribution of DOIs by ‘Zenodo’ and upload of files. / MIT	noarch
r-zendesk	0.4	This package provides an R wrapper for the Zendesk API / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-zic	0.9.1	Provides MCMC algorithms for the analysis of zero-inflated count models. The case of stochastic search variable selection (SVS) is also considered. All MCMC samplers are coded in C for improved efficiency. A data set considering the demand for health care is provided. / GPL-2	linux-64, osx-64, win-64
r-zillowr	0.1.0	Zillow, an online real estate company, provides real estate and mortgage data for the United States through a REST API. The ZillowR package provides an R function for each API service, making it easy to make API calls and process the response into convenient, R-friendly data structures. See < http://www.zillow.com/howto/api/APIOverview.htm > for the Zillow API Documentation. / GPL-3	noarch
r-zim	1.1.0	Analyze count time series with excess zeros. Two types of statistical models are supported: Markov regression by Yang et al. (2013) <doi:10.1016/j.stamet.2013.02.001> and state-space models by Yang et al. (2015) <doi:10.1177/1471082X14535530>. They are also known as observation-driven and parameter-driven models respectively in the time series literature. The functions used for Markov regression or observation-driven models can also be used to fit ordinary regression models with independent data under the zero-inflated Poisson (ZIP) or zero-inflated negative binomial (ZINB) assumption. Besides, the package contains some miscellaneous functions to compute density, distribution, quantile, and generate random numbers from ZIP and ZINB distributions. / GPL-3	noarch
r-zip	2.0.1	Cross-Platform ‘zip’ Compression Library. A replacement for the ‘zip’ function, that does not require any additional external tools on any platform. / CC0	linux-64, osx-64, win-32, win-64
r-zipcode	1.0	This package contains a database of city, state, latitude, and longitude information for U.S. ZIP codes from the CivicSpace Database (August 2004) augmented by Daniel Coven’s federalgovernmentzipcodes.us web site (updated January 22, 2012). Previous versions of this package (before 1.0) were based solely on the CivicSpace data, so an original version of the CivicSpace database is also included. / CC BY-SA 2.0 file LICENSE	noarch
r-zipfr	0.6.1	Statistical models and utilities for the analysis of word frequency distributions. The utilities include functions for loading, manipulating and visualizing word frequency data and vocabulary growth curves. The package also implements several statistical models for the distribution of word frequencies in a population. (The name of this package derives from the most famous word frequency distribution, Zipf’s law.) / GPL-3	noarch
r-zipr	0.1.1	Implements Python-style zip for R. Is a more flexible version of cbind. / GPL-3	noarch
r-zoeppritz	1.0.7	Calculate and plot scattering matrix coefficients for plane waves at interface. / GPL-2	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
r-zoo	1.8_6	An S3 class with methods for totally ordered indexed observations. It is particularly aimed at irregular time series of numeric vectors/matrices and factors. zoo's key design goals are independence of a particular index/date/time class and consistency with ts and base R by providing methods to extend standard generics. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
r-zoocat	0.2.0	Tools for manipulating multivariate time series data by extending 'zoo' class. / GPL-3	noarch
r-zoom	2.0.4	zm(), called with any active plot allow to enter an interactive session to zoom/navigate any plot. The development version, as well as binary releases can be found at https://github.com/cbarbu/R-package-zoom / GPL-3	noarch
r-zoomgrid	1.0.0	Provides the grid search algorithm with a zoom. The grid search algorithm with a zoom aims to help solving difficult optimization problem where there are many local optima inside the domain of the target function. It offers suitable initial or starting value for the following optimization procedure, provided that the global optimum exists in the neighbourhood of the initial or starting value. The grid search algorithm with a zoom saves time tremendously in cases with high-dimensional arguments. / GPL-3	noarch
r-zseq	0.2.0	Generates well-known integer sequences. 'gmp' package is adopted for computing with arbitrarily large numbers. Every function has hyperlink to its corresponding item in OEIS (The On-Line Encyclopedia of Integer Sequences) in the function help page. For interested readers, see Sloane and Plouffe (1995, ISBN:978-0125586306). / GPL-3	noarch
r-ztree	1.0.6	Read '.xls' and '.sbj' files which are written by the Microsoft Windows program 'z-Tree'. The latter is a software for developing and carrying out economic experiments (see http://www.ztree.uzh.ch/ for more information). / GPL-3	noarch
r.methodss3	1.7.1	Methods that simplify the setup of S3 generic functions and S3 methods. Major effort has been made in making definition of methods as simple as possible with a minimum of maintenance for package developers. For example, generic functions are created automatically, if missing, and naming conflict are automatically solved, if possible. The method setMethodS3() is a good start for those who in the future may want to migrate to S4. This is a cross-platform package implemented in pure R that generates standard S3 methods. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>r.oo</code>	1.22.0	Methods and classes for object-oriented programming in R with or without references. Large effort has been made on making definition of methods as simple as possible with a minimum of maintenance for package developers. The package has been developed since 2001 and is now considered very stable. This is a cross-platform package implemented in pure R that defines standard S3 classes without any tricks. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r.utils</code>	2.8.0	Utility functions useful when programming and developing R packages. / LGPL (>= 2.1)	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>r2d3</code>	0.2.3	Suite of tools for using 'D3', a library for producing dynamic, interactive data visualizations. Supports translating objects into 'D3' friendly data structures, rendering 'D3' scripts, publishing 'D3' visualizations, incorporating 'D3' in R Markdown, creating interactive 'D3' applications with Shiny, and distributing 'D3' based 'htmlwidgets' in R packages. / BSD_3_clause file LICENSE	noarch
<code>r6</code>	2.4.0	Creates classes with reference semantics, similar to R's built-in reference classes. Compared to reference classes, R6 classes are simpler and lighter-weight, and they are not built on S4 classes so they do not require the methods package. These classes allow public and private members, and they support inheritance, even when the classes are defined in different packages. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>randomforest</code>	4.6-14	Classification and regression based on a forest of trees using random inputs, based on Breiman (2001) <DOI:10.1023/A:1010933404324>. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
ranger	0.11.2	A fast implementation of Random Forests, particularly suited for high dimensional data. Ensembles of classification, regression, survival and probability prediction trees are supported. Data from genome-wide association studies can be analyzed efficiently. In addition to data frames, datasets of class 'gwaa.data' (R package 'GenABEL') and 'dgCMatrix' (R package 'Matrix') can be directly analyzed. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
rappdirs	0.3.1	An easy way to determine which directories on the users computer you should use to save data, caches and logs. A port of Python's 'Appdirs' (url{https://github.com/ActiveState/appdirs}) to R. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
raster	2.8.1	Reading, writing, manipulating, analyzing and modeling of gridded spatial data. The package implements basic and high-level functions. Processing of very large files is supported. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
rbokeh	0.6.3	A native R plotting library that provides a flexible declarative interface for creating interactive web-based graphics, backed by the Bokeh visualization library < http://bokeh.pydata.org/ >. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
rcmdcheck	1.3.2	Run 'R CMD check' from 'R' programmatically, and capture the results of the individual checks. / MIT file LICENSE	noarch

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rcolorbrewer	1.1_2	Provides color schemes for maps (and other graphics) designed by Cynthia Brewer as described at http://colorbrewer2.org / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
rcpp	1.0.1	The ‘Rcpp’ package provides R functions as well as C classes which offer a seamless integration of R and C. Many R data types and objects can be mapped back and forth to C equivalents which facilitates both writing of new code as well as easier integration of third-party libraries. Documentation about ‘Rcpp’ is provided by several vignettes included in this package, via the ‘Rcpp Gallery’ site at http://gallery.rcpp.org , the paper by Eddelbuettel and Francois (2011, <doi:10.18637/jss.v040.i08>), the book by Eddelbuettel (2013, <doi:10.1007/978-1-4614-6868-4>) and the paper by Eddelbuettel and Balamuta (2018, <doi:10.1080/00031305.2017.1375990>); see ‘citation(Rcpp)’ for details. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
rcpparmadillo	0.9.3002	‘RcppArmadillo’ is a templated C linear algebra library (by Conrad Sanderson) that aims towards a good balance between speed and ease of use. Integer, floating point and complex numbers are supported, as well as a subset of trigonometric and statistics functions. Various matrix decompositions are provided through optional integration with LAPACK and ATLAS libraries. The ‘RcppArmadillo’ package includes the header files from the templated ‘Armadillo’ library. Thus users do not need to install ‘Armadillo’ itself in order to use ‘RcppArmadillo’. From release 7.800.0 on, ‘Armadillo’ is licensed under Apache License 2; previous releases were under licensed as MPL 2.0 from version 3.800.0 onwards and LGPL-3 prior to that; ‘RcppArmadillo’ (the ‘Rcpp’ bindings/bridge to Armadillo) is licensed under the GNU GPL version 2 or later, as is the rest of ‘Rcpp’. Note that Armadillo requires a fairly recent compiler; for the g family at least version 4.6.* is required. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
rcppeigen	0.3.3.100	‘RcppEigen’ and ‘Eigen’ integration using ‘Rcpp’. ‘Eigen’ is a C template library for linear algebra: matrices, vectors, numerical solvers and related algorithms. It supports dense and sparse matrices on integer, floating point and complex numbers, decompositions of such matrices, and solutions of linear systems. Its performance on many algorithms is comparable with some of the best implementations based on ‘Lapack’ and level-3 ‘BLAS’. The ‘RcppEigen’ package includes the header files from the ‘Eigen’ C template library (currently version 3.3.4). Thus users do not need to install ‘Eigen’ itself in order to use ‘RcppEigen’. Since version 3.1.1, ‘Eigen’ is licensed under the Mozilla Public License (version 2); earlier version were licensed under the GNU LGPL version 3 or later. ‘RcppEigen’ (the ‘Rcpp’ bindings/bridge to ‘Eigen’) is licensed under the GNU GPL version 2 or later, as is the rest of ‘Rcpp’. / GPL (>= 2) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
rcppprogress	0.4.1	Allows to display a progress bar in the R console for long running computations taking place in c code, and support for interrupting those computations even in multithreaded code, typically using OpenMP. / GPL (>= 3)	noarch

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rcpproll	0.3.0	Provides fast and efficient routines for common rolling / windowed operations. Routines for the efficient computation of windowed mean, median, sum, product, minimum, maximum, standard deviation and variance are provided. / GPL (≥ 2)	linux-32, linux-64, osx-64, win-32, win-64
rcurl	1.95	Wrapper for 'libcurl' < http://curl.haxx.se/libcurl/ > Provides functions to allow one to compose general HTTP requests and provides convenient functions to fetch URIs, get & post forms, etc. and process the results returned by the Web server. This provides a great deal of control over the HTTP/FTP... connection and the form of the request while providing a higher-level interface than is available just using R socket connections. Additionally, the underlying implementation is robust and extensive, supporting FTP/FTPS/TFTP (uploads and downloads), SSL/HTTPS, telnet, dict, ldap, and also supports cookies, redirects, authentication, etc. / BSD	linux-32, linux-64, osx-64, win-32, win-64
readr	1.3.1	The goal of 'readr' is to provide a fast and friendly way to read rectangular data (like 'csv', 'tsv', and 'fwf'). It is designed to flexibly parse many types of data found in the wild, while still cleanly failing when data unexpectedly changes. / GPL (≥ 2) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
readxl	1.3.1	Import excel files into R. Supports '.xls' via the embedded 'libxls' C library < https://github.com/libxls/libxls > and '.xlsx' via the embedded 'RapidXML' C library < http://rapidxml.sourceforge.net >. Works on Windows, Mac and Linux without external dependencies. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
recipes	0.1.5	An extensible framework to create and preprocess design matrices. Recipes consist of one or more data manipulation and analysis steps. Statistical parameters for the steps can be estimated from an initial data set and then applied to other data sets. The resulting design matrices can then be used as inputs into statistical or machine learning models. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
recommended	3.6.0	R is a free software environment for statistical computing and graphics. / GPL-3.0	linux-32, linux-64, osx-64, win-32, win-64
registry	0.5.1	Provides a generic infrastructure for creating and using registries. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
rematch	1.0.1	A small wrapper on 'regexpr' to extract the matches and captured groups from the match of a regular expression to a character vector. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
remotes	2.0.4	Download and install R packages stored in 'GitHub', 'BitBucket', or plain 'subversion' or 'git' repositories. This package provides the 'install_*' functions in 'devtools'. Indeed most of the code was copied over from 'devtools'. / GPL (>= 2)	noarch
repr	0.19.2	String and binary representations of objects for several formats / mime types. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
reprex	0.2.1	Convenience wrapper that uses the ‘rmarkdown’ package to render small snippets of code to target formats that include both code and output. The goal is to encourage the sharing of small, reproducible, and runnable examples on code-oriented websites, such as < https://stackoverflow.com > and < https://github.com >, or in email. The user’s clipboard is the default source of input code and the default target for rendered output. ‘reprex’ also extracts clean, runnable R code from various common formats, such as copy/paste from an R session. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
reshape	0.8.8	Flexibly restructure and aggregate data using just two functions: melt and cast. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
reshape2	1.4.3	Flexibly restructure and aggregate data using just two functions: melt and ‘dcast’ (or ‘acast’). / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
reticulate	1.12	Interface to ‘Python’ modules, classes, and functions. When calling into ‘Python’, R data types are automatically converted to their equivalent ‘Python’ types. When values are returned from ‘Python’ to R they are converted back to R types. Compatible with all versions of ‘Python’ >= 2.7. / Apache License 2.0	linux-32, linux-64, osx-64, win-32, win-64
revoioq	10.0.0	Test suite for Microsoft R Services. / GPL-2	linux-64, osx-64, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
revomods	11.0.0	Microsoft modifications and extensions to standard R functions / GPL-2	linux-64, osx-64, win-64
revoutils	11.0.0	Utility functions for Microsoft R / GPL-2	linux-64, osx-64, win-64
revoutilsmath	11.0.0	Utility functions for managing math threading. / file LICENSE	linux-64, win-64
rex	1.1.2	A friendly interface for the construction of regular expressions. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
rgexf	0.15.3	Create, read and write GEXF (Graph Exchange XML Format) graph files (used in Gephi and others). Using the XML package, it allows the user to easily build/read graph files including attributes, GEXF viz attributes (such as color, size, and position), network dynamics (for both edges and nodes) and edge weighting. Users can build/handle graphs element-by-element or massively through data-frames, visualize the graph on a web browser through sigma.js (a javascript library) and interact with the igraph package. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
rgl	0.100.10	Provides medium to high level functions for 3D interactive graphics, including functions modelled on base graphics (plot3d(), etc.) as well as functions for constructing representations of geometric objects (cube3d(), etc.). Output may be on screen using OpenGL, or to various standard 3D file formats including WebGL, PLY, OBJ, STL as well as 2D image formats, including PNG, Postscript, SVG, PGF. / GPL	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rglwidget	0.2.1	The contents of this package have been merged into rgl, so it is no longer needed. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
rhive	2.0_0	R Hive is an R extension facilitating distributed computing via HIVE query. It provides an easy to use HQL like SQL and R objects and functions in HQL. / Apache License (== 2.0)	linux-32, linux-64, osx-64, win-32, win-64
rio	0.5.1	Streamlined data import and export by making assumptions that the user is probably willing to make: 'import()' and 'export()' determine the data structure from the file extension, reasonable defaults are used for data import and export (e.g., 'stringsAsFactors=FALSE'), web-based import is natively supported (including from SSL/HTTPS), compressed files can be read directly without explicit decompression, and fast import packages are used where appropriate. An additional convenience function, 'convert()', provides a simple method for converting between file types. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
rjava	0.9_1	Low-level interface to Java VM very much like .C/.Call and friends. Allows creation of objects, calling methods and accessing fields. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rjdbc	0.2_7	The RJDBC package is an implementation of R's DBI interface using JDBC as a back-end. This allows R to connect to any DBMS that has a JDBC driver. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
rjson	0.2.20	Converts R object into JSON objects and vice-versa. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
rjsonio	1.3_1	This is a package that allows conversion to and from data in Javascript object notation (JSON) format. This allows R objects to be inserted into Javascript/ECMAScript/ActionScript code and allows R programmers to read and convert JSON content to R objects. This is an alternative to rjson package. Originally, that was too slow for converting large R objects to JSON and was not extensible. rjson's performance is now similar to this package, and perhaps slightly faster in some cases. This package uses methods and is readily extensible by defining methods for different classes, vectorized operations, and C code and callbacks to R functions for deserializing JSON objects to R. The two packages intentionally share the same basic interface. This package (RJSONIO) has many additional options to allow customizing the generation and processing of JSON content. This package uses libjson rather than implementing yet another JSON parser. The aim is to support other general projects by building on their work, providing feedback and benefit from their ongoing development. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
rlang	0.3.4	A toolbox for working with base types, core R features like the condition system, and core 'Tidyverse' features like tidy evaluation. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>rlist</code>	0.4.6	Provides a set of functions for data manipulation with list objects, including mapping, filtering, grouping, sorting, updating, searching, and other useful functions. Most functions are designed to be pipeline friendly so that data processing with lists can be chained. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>rmariadb</code>	1.0.6	Implements a 'DBI'-compliant interface to 'MariaDB' (< https://mariadb.org/ >) and 'MySQL' (< https://www.mysql.com/ >) databases. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
<code>rmarkdown</code>	1.12	Convert R Markdown documents into a variety of formats. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>rmr2</code>	3.3.1	Supports the map reduce programming model on top of hadoop streaming / Apache 2.0	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rms	5.1_3	Regression modeling, testing, estimation, validation, graphics, prediction, and typesetting by storing enhanced model design attributes in the fit. ‘rms’ is a collection of functions that assist with and streamline modeling. It also contains functions for binary and ordinal logistic regression models, ordinal models for continuous Y with a variety of distribution families, and the Buckley-James multiple regression model for right-censored responses, and implements penalized maximum likelihood estimation for logistic and ordinary linear models. ‘rms’ works with almost any regression model, but it was especially written to work with binary or ordinal regression models, Cox regression, accelerated failure time models, ordinary linear models, the Buckley-James model, generalized least squares for serially or spatially correlated observations, generalized linear models, and quantile regression. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
rmysql	0.10.1	Legacy ‘DBI’ interface to ‘MySQL’ / ‘MariaDB’ based on old code ported from S-PLUS. A modern ‘MySQL’ client based on ‘Rcpp’ is available from the ‘RMariaDB’ package. / GPL-2	linux-32, linux-64, osx-64, win-64
rngtools	1.3.1	Provides a set of functions for working with Random Number Generators (RNGs). In particular, a generic S4 framework is defined for getting/setting the current RNG, or RNG data that are embedded into objects for reproducibility. Notably, convenient default methods greatly facilitate the way current RNG settings can be changed. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
robustbase	0.93_4	Essential Robust Statistics. Tools allowing to analyze data with robust methods. This includes regression methodology including model selections and multivariate statistics where we strive to cover the book Robust Statistics, Theory and Methods by ‘Maronna, Martin and Yohai’; Wiley 2006. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rocr	1.0_7	ROC graphs, sensitivity/specificity curves, lift charts, and precision/recall plots are popular examples of trade-off visualizations for specific pairs of performance measures. ROCR is a flexible tool for creating cutoff-parameterized 2D performance curves by freely combining two from over 25 performance measures (new performance measures can be added using a standard interface). Curves from different cross-validation or bootstrapping runs can be averaged by different methods, and standard deviations, standard errors or box plots can be used to visualize the variability across the runs. The parameterization can be visualized by printing cutoff values at the corresponding curve positions, or by coloring the curve according to cutoff. All components of a performance plot can be quickly adjusted using a flexible parameter dispatching mechanism. Despite its flexibility, ROCR is easy to use, with only three commands and reasonable default values for all optional parameters. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
rodbc	1.3_15	An ODBC database interface. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
rook	1.1_1	This package contains the Rook specification and convenience software for building and running Rook applications. To get started, be sure and read the ‘Rook’ help file first. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
roxygen2	6.1.1	Generate your Rd documentation, ‘NAMESPACE’ file, and collation field using specially formatted comments. Writing documentation in-line with code makes it easier to keep your documentation up-to-date as your requirements change. ‘Roxygen2’ is inspired by the ‘Doxygen’ system for C. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rpanel	1.1_4	A set of functions to build simple GUI controls for R functions. These are built on the ‘tcltk’ package. Uses could include changing a parameter on a graph by animating it with a slider or a doublebutton, up to more sophisticated control panels. Some functions for specific graphical tasks, referred to as ‘cartoons’, are provided. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
rpart	4.1_1	Recursive partitioning for classification, regression and survival trees. An implementation of most of the functionality of the 1984 book by Breiman, Friedman, Olshen and Stone. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
rprojroot	1.3_2	Robust, reliable and flexible paths to files below a project root. The ‘root’ of a project is defined as a directory that matches a certain criterion, e.g., it contains a certain regular file. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
rpy2	2.9.4	Python interface to the R language (embedded R) / GPL2	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
rsconnect	0.8.13	Programmatic deployment interface for ‘Rpubs’, ‘shinyapps.io’, and ‘RStudio Connect’. Supported content types include R Markdown documents, Shiny applications, Plumber APIs, plots, and static web content. / GPL-2	linux-32, linux-64, noarch, osx-64, win-32, win-64
rserve	1.7.3	Rserve acts as a socket server (TCP/IP or local sockets) which allows binary requests to be sent to R. Every connection has a separate workspace and working directory. Client-side implementations are available for popular languages such as C/C and Java, allowing any application to use facilities of R without the need of linking to R code. Rserve supports remote connection, user authentication and file transfer. A simple R client is included in this package as well. / GPL-2 file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
rsqlite	2.1.1	Embeds the ‘SQLite’ database engine in R and provides an interface compliant with the ‘DBI’ package. The source for the ‘SQLite’ engine is included. / LGPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
rstan	2.18.2	User-facing R functions are provided to parse, compile, test, estimate, and analyze Stan models by accessing the header-only Stan library provided by the ‘StanHeaders’ package. The Stan project develops a probabilistic programming language that implements full Bayesian statistical inference via Markov Chain Monte Carlo, rough Bayesian inference via ‘variational’ approximation, and (optionally penalized) maximum likelihood estimation via optimization. In all three cases, automatic differentiation is used to quickly and accurately evaluate gradients without burdening the user with the need to derive the partial derivatives. / GPL (>= 3)	linux-32, linux-64, osx-64, win-32, win-64
rstudio	1.1.456	A set of integrated tools designed to help you be more productive with R / Commercial or AGPLv3	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 51 – continued from previous page

Name	Version	Summary/License	Platforms
<code>rstudioapi</code>	0.10	Access the RStudio API (if available) and provide informative error messages when it's not. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>rtools</code>	3.4.0	None / None	win-64
<code>runit</code>	0.4.26	R functions implementing a standard Unit Testing framework, with additional code inspection and report generation tools / GPL-2	linux-64, osx-64, win-64
<code>rversions</code>	1.1.0	Query the main 'R' 'SVN' repository to find the versions 'r-release' and 'r-oldrel' refer to, and also all previous 'R' versions and their release dates. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>rvest</code>	0.3.3	Wrappers around the 'xml2' and 'httr' packages to make it easy to download, then manipulate, HTML and XML. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>rzmq</code>	0.9.6	Interface to the 'ZeroMQ' lightweight messaging kernel (see < http://www.zeromq.org/ > for more information). / GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Table 52: S

Name	Version	Summary/License	Platforms
sandwich	2.5_1	Model-robust standard error estimators for cross-sectional, time series, clustered, panel, and longitudinal data. / GPL-2 GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
scales	1.0.0	Graphical scales map data to aesthetics, and provide methods for automatically determining breaks and labels for axes and legends. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
seacarb	3.2.12	Calculates parameters of the seawater carbonate system and assists the design of ocean acidification perturbation experiments. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
selectr	0.4_1	Translates a CSS3 selector into an equivalent XPath expression. This allows us to use CSS selectors when working with the XML package as it can only evaluate XPath expressions. Also provided are convenience functions useful for using CSS selectors on XML nodes. This package is a port of the Python package 'cssselect' (< https://cssselect.readthedocs.io/ >). / BSD_3_clause file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
sessioninfo	1.1.1	Query and print information about the current R session. It is similar to 'utils::sessionInfo()', but includes more information about packages, and where they were installed from. / GPL-2	noarch

Continued on next page

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
sf	0.6_3	Support for simple features, a standardized way to encode spatial vector data. Binds to 'GDAL' for reading and writing data, to 'GEOS' for geometrical operations, and to 'PROJ' for projection conversions and datum transformations. / GPL-2 MIT file LICENSE	linux-32, linux-64, osx-64, win-64
sfsmisc	1.1_3	Useful utilities ['goodies'] from Seminar fuer Statistik ETH Zurich, some of which were ported from S-plus in the 1990's. For graphics, have pretty (Log-scale) axes, an enhanced Tukey-Anscombe plot, combining histogram and boxplot, 2d-residual plots, a 'tachoPlot()', pretty arrows, etc. For robustness, have a robust F test and robust range(). For system support, notably on Linux, provides 'Sys.*()' functions with more access to system and CPU information. Finally, miscellaneous utilities such as simple efficient prime numbers, integer codes, Duplicated(), toLatex.numeric() and is.whole(). / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
shiny	1.3.2	Makes it incredibly easy to build interactive web applications with R. Automatic reactive binding between inputs and outputs and extensive prebuilt widgets make it possible to build beautiful, responsive, and powerful applications with minimal effort. / GPL-3 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
shinybs	0.61	Adds additional Twitter Bootstrap components to Shiny. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
shinycssloaders	0.2.0	Create a lightweight Shiny wrapper for the css-loaders created by Luke Hass < https://github.com/lukehaas/css-loaders >. Wrapping a Shiny output will automatically show a loader when the output is (re)calculating. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
shinydashboard	0.7.1	Create dashboards with ‘Shiny’. This package provides a theme on top of ‘Shiny’, making it easy to create attractive dashboards. / GPL (>= 2) file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
shinyjs	1.0	Perform common useful JavaScript operations in Shiny apps that will greatly improve your apps without having to know any JavaScript. Examples include: hiding an element, disabling an input, resetting an input back to its original value, delaying code execution by a few seconds, and many more useful functions for both the end user and the developer. ‘shinyjs’ can also be used to easily call your own custom JavaScript functions from R. / AGPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
shinysky	2.0.0	A set of Shiny UI components includings alerts and styled buttons / MIT	linux-32, linux-64, osx-64, win-32, win-64

Continued on next page

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
shinythemes	1.1.2	Themes for use with Shiny. Includes several Bootstrap themes from http://bootswatch.com/ , which are packaged for use with Shiny applications. / GPL-3 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
slam	0.1_4	Data structures and algorithms for sparse arrays and matrices, based on index arrays and simple triplet representations, respectively. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
snowballc	0.6.0	An R interface to the C ‘libstemmer’ library that implements Porter’s word stemming algorithm for collapsing words to a common root to aid comparison of vocabulary. Currently supported languages are Danish, Dutch, English, Finnish, French, German, Hungarian, Italian, Norwegian, Portuguese, Romanian, Russian, Spanish, Swedish and Turkish. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
sourcetools	0.1.7	Tools for the reading and tokenization of R code. The ‘sourcetools’ package provides both an R and C interface for the tokenization of R code, and helpers for interacting with the tokenized representation of R code. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
sp	1.3_1	Classes and methods for spatial data; the classes document where the spatial location information resides, for 2D or 3D data. Utility functions are provided, e.g. for plotting data as maps, spatial selection, as well as methods for retrieving coordinates, for subsetting, print, summary, etc. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
sparklyr	1.0.0	R interface to Apache Spark, a fast and general engine for big data processing, see < http://spark.apache.org >. This package supports connecting to local and remote Apache Spark clusters, provides a ‘dplyr’ compatible back-end, and provides an interface to Spark’s built-in machine learning algorithms. / Apache License 2.0 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
sparsem	1.77	Some basic linear algebra functionality for sparse matrices is provided: including Cholesky decomposition and backsolving as well as standard R subsetting and Kronecker products. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
spatial	7.3_1	Functions for kriging and point pattern analysis. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64
spdata	0.3.0	Diverse spatial datasets for demonstrating, benchmarking and teaching spatial data analysis. It includes R data of class sf (defined by the package ‘sf’), Spatial (‘sp’), and nb (‘spdep’). Unlike other spatial data packages such as ‘rnat-uralearth’ and ‘maps’, it also contains data stored in a range of file formats including GeoJSON, ESRI Shapefile and GeoPackage. Some of the datasets are designed to illustrate specific analysis techniques. cycle_hire() and cycle_hire_osm(), for example, is designed to illustrate point pattern analysis techniques. / CC0	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
squarem	2017.10	Algorithms for accelerating the convergence of slow, monotone sequences from smooth, contraction mapping such as the EM algorithm. It can be used to accelerate any smooth, linearly convergent acceleration scheme. A tutorial style introduction to this package is available in a vignette on the CRAN download page or, when the package is loaded in an R session, with vignette(SQUAREM). / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
stabledist	0.7_1	Density, Probability and Quantile functions, and random number generation for (skew) stable distributions, using the parametrizations of Nolan. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
stanheaders	2.18.1	The C header files of the Stan project are provided by this package, but it contains no R code or function documentation. There is a shared object containing part of the 'CVODES' library, but it is not accessible from R. 'StanHeaders' is only useful for developers who want to utilize the 'LinkingTo' directive of their package's DESCRIPTION file to build on the Stan library without incurring unnecessary dependencies. The Stan project develops a probabilistic programming language that implements full or approximate Bayesian statistical inference via Markov Chain Monte Carlo or 'variational' methods and implements (optionally penalized) maximum likelihood estimation via optimization. The Stan library includes an advanced automatic differentiation scheme, 'templated' statistical and linear algebra functions that can handle the automatically 'differentiable' scalar types (and doubles, 'ints', etc.), and a parser for the Stan language. The 'rstan' package provides user-facing R functions to parse, compile, test, estimate, and analyze Stan models. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
stopwords	0.9.0	Provides multiple sources of stopwords, for use in text analysis and natural language processing. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
<code>stringdist</code>	0.9.5	Implements an approximate string matching version of R's native 'match' function. Can calculate various string distances based on edits (Damerau-Levenshtein, Hamming, Levenshtein, optimal sting alignment), qgrams (q-gram, cosine, jaccard distance) or heuristic metrics (Jaro, Jaro-Winkler). An implementation of soundex is provided as well. Distances can be computed between character vectors while taking proper care of encoding or between integer vectors representing generic sequences. This package is built for speed and runs in parallel by using 'openMP'. An API for C or C is exposed as well. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
<code>stringi</code>	1.4.3	Fast, correct, consistent, portable, as well as convenient character string/text processing in every locale and any native encoding. Owing to the use of the 'ICU' (International Components for Unicode) library, the package provides 'R' users with platform-independent functions known to 'Java', 'Perl', 'Python', 'PHP', and 'Ruby' programmers. Available features include: pattern searching (e.g., with 'Java'-like regular expressions or the 'Unicode' collation algorithm), random string generation, case mapping, string transliteration, concatenation, Unicode normalization, date-time formatting and parsing, and many more. / file LICENSE (FOSS)	linux-32, linux-64, osx-64, win-32, win-64
<code>stringr</code>	1.4.0	A consistent, simple and easy to use set of wrappers around the fantastic 'stringi' package. All function and argument names (and positions) are consistent, all functions deal with NA's and zero length vectors in the same way, and the output from one function is easy to feed into the input of another. / GPL-2 file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
<code>strucchange</code>	1.5_1	Testing, monitoring and dating structural changes in (linear) regression models. strucchange features tests/methods from the generalized fluctuation test framework as well as from the F test (Chow test) framework. This includes methods to fit, plot and test fluctuation processes (e.g., CUSUM, MOSUM, recursive/moving estimates) and F statistics, respectively. It is possible to monitor incoming data online using fluctuation processes. Finally, the breakpoints in regression models with structural changes can be estimated together with confidence intervals. Emphasis is always given to methods for visualizing the data. / GPL-2 GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64

Continued on next page

Table 52 – continued from previous page

Name	Version	Summary/License	Platforms
suppdists	1.1_9.4	Ten distributions supplementing those built into R. Inverse Gauss, Kruskal-Wallis, Kendall's Tau, Friedman's chi squared, Spearman's rho, maximum F ratio, the Pearson product moment correlation coefficient, Johnson distributions, normal scores and generalized hypergeometric distributions. In addition two random number generators of George Marsaglia are included. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
survival	2.44_1	Contains the core survival analysis routines, including definition of Surv objects, Kaplan-Meier and Aalen-Johansen (multi-state) curves, Cox models, and parametric accelerated failure time models. / LGPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
sys	3.2	Drop-in replacements for the base system2() function with fine control and consistent behavior across platforms. Supports clean interruption, timeout, background tasks, and streaming STDIN / STDOUT / STDERR over binary or text connections. Arguments on Windows automatically get encoded and quoted to work on different locales. / MIT file LICENSE	linux-64, osx-64, win-32, win-64

Table 53: T

Name	Version	Summary/License	Platforms
tensorflow	1.13.1	Interface to ‘TensorFlow’ < https://www.tensorflow.org/ >, an open source software library for numerical computation using data flow graphs. Nodes in the graph represent mathematical operations, while the graph edges represent the multidimensional data arrays (tensors) communicated between them. The flexible architecture allows you to deploy computation to one or more ‘CPUs’ or ‘GPUs’ in a desktop, server, or mobile device with a single ‘API’. ‘TensorFlow’ was originally developed by researchers and engineers working on the Google Brain Team within Google’s Machine Intelligence research organization for the purposes of conducting machine learning and deep neural networks research, but the system is general enough to be applicable in a wide variety of other domains as well. / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
testit	0.9	Provides two convenience functions <code>assert()</code> and <code>test_pkg()</code> to facilitate testing R packages. / GPL	linux-32, linux-64, noarch, osx-64, win-32, win-64
testthat	2.1.1	Software testing is important, but, in part because it is frustrating and boring, many of us avoid it. ‘testthat’ is a testing framework for R that is easy learn and use, and integrates with your existing ‘workflow’. / MIT file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
tfruns	1.4	Create and manage unique directories for each ‘TensorFlow’ training run. Provides a unique, time stamped directory for each run along with functions to retrieve the directory of the latest run or latest several runs. / Apache License 2.0	linux-32, linux-64, noarch, osx-64, win-32, win-64
th.data	1.0_10	Contains data sets used in other packages Torsten Hothorn maintains. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
2392		Chapter 4. Anaconda Cloud	
threejs	0.3.1	Create interactive 3D scatter plots, network plots, and globes using the ‘three.js’ visualization library (< https://threejs.org/ >). / MIT file LICENSE	linux-32, linux-

Table 54: U

Name	Version	Summary/License	Platforms
udunits2	0.13	Provides simple bindings to Unidata's udunits library. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
units	0.6_2	Support for measurement units in R vectors, matrices and arrays: automatic propagation, conversion, derivation and simplification of units; raising errors in case of unit incompatibility. Compatible with the POSIXct, Date and diff-time classes. Uses the UNIDATA udunits library and unit database for unit compatibility checking and conversion. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
urca	1.3_0	Unit root and cointegration tests encountered in applied econometric analysis are implemented. / GPL (>= 2)	linux-32, linux-64, osx-64, win-32, win-64
uroot	2.0_9	Seasonal unit roots and seasonal stability tests. P-values based on response surface regressions are available for both tests. P-values based on bootstrap are available for seasonal unit root tests. A parallel implementation of the bootstrap method requires a CUDA capable GPU with compute capability >= 3.0, otherwise a debugging version fully coded in R is used. / GPL-2	linux-32, linux-64, osx-64, win-32, win-64
usethis	1.5.0	Automate package and project setup tasks that are otherwise performed manually. This includes setting up unit testing, test coverage, continuous integration, Git, 'GitHub', licenses, 'Rcpp', 'RStudio' projects, and more. / GPL-3	noarch
utf8	1.1.4	Process and print 'UTF-8' encoded international text (Unicode). Input, validate, normalize, encode, format, and display. / Apache License (== 2.0) file LICENSE	linux-32, linux-64, osx-64, win-32, win-64
uuid	0.1_2	Tools for generating and handling of UUIDs (Universally Unique Identifiers). / MIT file LICENSE	linux-32, linux-64,

Table 55: V

Name	Version	Summary/License	Platforms
vars	1.5_3	Estimation, lag selection, diagnostic testing, forecasting, causality analysis, forecast error variance decomposition and impulse response functions of VAR models and estimation of SVAR and SVEC models. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64
vgam	1.1_1	An implementation of about 6 major classes of statistical regression models. The central algorithm is Fisher scoring and iterative reweighted least squares. At the heart of this package are the vector generalized linear and additive model (VGLM/VGAM) classes. VGLMs can be loosely thought of as multivariate GLMs. VGAMs are data-driven VGLMs that use smoothing. The book Vector Generalized Linear and Additive Models: With an Implementation in R (Yee, 2015) <DOI:10.1007/978-1-4939-2818-7> gives details of the statistical framework and the package. Currently only fixed-effects models are implemented. Many (150) models and distributions are estimated by maximum likelihood estimation (MLE) or penalized MLE. The other classes are RR-VGLMs (reduced-rank VGLMs), quadratic RR-VGLMs, reduced-rank VGAMs, RCIMs (row-column interaction models)—these classes perform constrained and unconstrained quadratic ordination (CQO/UQO) models in ecology, as well as constrained additive ordination (CAO). Note that these functions are subject to change; see the NEWS and ChangeLog files for latest changes. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
viridis	0.5.1	Implementation of the ‘viridis’ - the default -, ‘magma’, ‘plasma’, ‘inferno’, and ‘cividis’ color maps for ‘R’. ‘viridis’, ‘magma’, ‘plasma’, and ‘inferno’ are ported from ‘matplotlib’ < http://matplotlib.org/ >, a popular plotting library for ‘python’. ‘cividis’, was developed by Jamie R. Nuñez and Sean M. Colby. These color maps are designed in such a way that they will analytically be perfectly perceptually-uniform, both in regular form and also when converted to black-and-white. They are also designed to be perceived by readers with the most common form of color blindness (all color maps in this package) and color vision deficiency (‘cividis’ only). / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
viridislite	0.3.0	Implementation of the ‘viridis’ - the default -, ‘magma’, ‘plasma’, ‘inferno’, and ‘cividis’ color maps for ‘R’. ‘viridis’, ‘magma’, ‘plasma’, and ‘inferno’ are ported from ‘matplotlib’ < http://matplotlib.org/ >, a popular plotting library for ‘python’. ‘cividis’, was developed by Jamie R. Nuñez and Sean M. Colby. These color maps are designed in such a way that they will analytically be perfectly perceptually-uniform, both in regular form and also when converted to black-and-white. They are also designed to be perceived by readers with the most common form of color blindness (all color maps in this package) and color vision deficiency (‘cividis’ only). This is the ‘lite’ version of the more complete ‘viridis’ package that can be found at < https://cran.r-project.org/package=viridis >. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
visnetwork	2.0.6	Provides an R interface to the ‘vis.js’ JavaScript charting library. It allows an interactive visualization of networks. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-32, win-64
2394		Chapter 4. Anaconda Cloud	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 56: W

Name	Version	Summary/License	Platforms
weatherdata	0.5.0	Functions that help in fetching weather data from websites. Given a location and a date range, these functions help fetch weather data (temperature, pressure etc.) for any weather related analysis. / GPL	linux-32, linux-64, osx-64, win-32, win-64
webshot	0.5.1	Takes screenshots of web pages, including Shiny applications and R Markdown documents. / GPL-2	linux-64, noarch, osx-64, win-32, win-64
whisker	0.3.2	logicless templating, reuse templates in many programming languages including R / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
withr	2.1.2	A set of functions to run code ‘with’ safely and temporarily modified global state. Many of these functions were originally a part of the ‘devtools’ package, this provides a simple package with limited dependencies to provide access to these functions. / GPL (>= 2)	linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 57: X

Name	Version	Summary/License	Platforms
x13binary	1.1.39	The US Census Bureau provides a seasonal adjustment program now called ‘X-13ARIMA-SEATS’ building on both earlier programs called X-11 and X-12 as well as the SEATS program by the Bank of Spain. The US Census Bureau offers both source and binary versions – which this package integrates for use by other R packages. / file LICENSE	linux-64, noarch, osx-64, win-32, win-64
xfun	0.6	Miscellaneous functions commonly used in other packages maintained by ‘Yihui Xie’. / MIT file LICENSE	linux-64, noarch, osx-64, win-32, win-64
xgboost	0.80	eXtreme Gradient Boosting / Apache-2	linux-32, linux-64, osx-64, win-32, win-64
xgboost-cpu	0.80	None / None	linux-64, osx-64, win-64
xgboost-gpu	0.80	None / None	linux-64
xlsx	0.6.1	Provide R functions to read/write/format Excel 2007 and Excel 97/2000/XP/2003 file formats. / GPL-3	linux-32, linux-64, noarch, osx-64, win-32, win-64
xlsxjars	0.6.1	The xlsxjars package collects all the external jars required for the xlsx package. This release corresponds to POI 3.10.1. / GPL-3	linux-32, linux-64, osx-64, win-32, win-64
2396			linux-32, linux-64, noarch, osx-64, win-32, win-64

Table 58: Y

Name	Version	Summary/License	Platforms
yaml	2.2.0	Implements the ‘libyaml’ ‘YAML’ 1.1 parser and emitter (< http://pyyaml.org/wiki/LibYAML >) for R. / BSD_3_clause file LICENSE	linux-32, linux-64, osx-64, win-32, win-64

Table 59: Z

Name	Version	Summary/License	Platforms
zeallot	0.1.0	Provides a %<-% operator to perform multiple, unpacking, and destructuring assignment in R. The operator unpacks the right-hand side of an assignment into multiple values and assigns these values to variables on the left-hand side of the assignment. / MIT file LICENSE	linux-32, linux-64, noarch, osx-64, win-64
zip	2.0.1	Cross-Platform ‘zip’ Compression Library. A replacement for the ‘zip’ function, that does not require any additional external tools on any platform. / CC0	linux-64, osx-64, win-32, win-64
zoo	1.8_5	An S3 class with methods for totally ordered indexed observations. It is particularly aimed at irregular time series of numeric vectors/matrices and factors. zoo’s key design goals are independence of a particular index/date/time class and consistency with ts and base R by providing methods to extend standard generics. / GPL-2 GPL-3	linux-32, linux-64, osx-64, win-32, win-64

Documentation download packages

For users who wish to view documentation locally or when offline, Anaconda provides documentation downloads.

Anaconda documentation downloads

docs.anaconda.com includes documentation for these products:

- [*Anaconda Distribution*](#)
- [*Anaconda Navigator*](#)
- [*Anaconda Enterprise 4 Repository*](#)
- [*Anaconda Enterprise 4 Notebooks*](#)
- [*Anaconda Cloud*](#)
- [*MKL Optimizations*](#)

[docs.anaconda.com](#) also includes archived documentation pages for these products that are no longer in production:

- [*Anaconda Accelerate*](#)
- [*Anaconda Adam*](#)
- [*Anaconda for Cluster Management*](#)
- [*Anaconda Launcher*](#)
- [*Anaconda Scale*](#)
- [*NumbaPro*](#)

You can download a PDF or zipped HTML copy of [docs.anaconda.com](#) by clicking the v: latest box in the lower right corner. Under the heading “Downloads” you will see the options “PDF” and “HTML”.

[enterprise-docs.anaconda.com](#) offers documentation for Anaconda Enterprise 5.

You can download a PDF or zipped HTML copy of [enterprise-docs.anaconda.com](#) by navigating to that site and clicking the v: latest box in the lower right corner. Under the heading “Downloads” you will see the options “PDF” and “HTML”.

You can install offline copies of both [docs.anaconda.com](#) and [enterprise-docs.anaconda.com](#) by installing the conda package `anaconda-docs`:

```
conda install anaconda-docs
```

This will install a PDF copy and a zipped HTML copy of each site into the directory `share/doc` for your currently active conda environment.

EXAMPLE: If your conda install directory is `~/miniconda3`, and your environment is named `my-env`, the documentation will be installed into `~/miniconda3/envs/my-env/share/doc/`.

Open-source package documentation downloads

You can download a package of documentation for many of Anaconda’s open-source packages with this command:

```
conda install anaconda-oss-docs
```

This will install documentation for the open-source packages into the directory `share/doc/anaconda-oss` for your currently active conda environment.

EXAMPLE: If your conda install directory is `~/miniconda3`, and your environment is named `my-env`, the documentation will be installed into `~/miniconda3/envs/my-env/share/doc/anaconda-oss`.

This bundle includes documentation for these packages:

- Python
- NumPy

- SciPy
- pandas
- Conda
- Blaze
- Bleach
- botocore
- Certifi
- cryptography
- CFFI
- coverage
- Cython
- Dask
- Dask.distributed
- dateutil
- greenlet
- h5py
- html5lib
- imageio
- IPython
- Jinja
- Jupyter
- JupyterLab
- Jupyter Notebook
- llvmlite
- msgpack
- Odo
- OpenSSL
- Pillow
- pip
- psutil
- pyOpenSSL
- python-tblib
- PyWavelets
- PyZMQ
- Requests
- ruamel.yaml

- Setuptools
- six
- toolz
- Tornado
- Traitlets
- wheel
- Zict

Old package lists

You can download previous versions of Anaconda from the [Anaconda installer archive](#).

Older versions of packages can usually be downloaded from the [package repository](#) or from <https://anaconda.org/anaconda/PackageName>.

Note: Replace `PackageName` with the name of the desired package.

EXAMPLE: At <https://anaconda.org/anaconda/beautifulsoup4>, previous versions of beautifulsoup4 are shown on the **Files** tab.

You can also search for packages from the command line with `conda search PackageName`.

4.2.4 End User License Agreement - Anaconda® Individual Edition

© 2015-2020, Anaconda, Inc.

All rights reserved under the 3-clause BSD License:

This End User License Agreement (the “Agreement”) is a legal agreement between you and Anaconda, Inc. (“Anaconda”) and governs your use of Anaconda® Individual Edition (which was formerly known as Anaconda® Distribution).

Subject to the terms of this Agreement, Anaconda hereby grants you a non-exclusive, non-transferable license to:

- Install and use the Anaconda® Individual Edition (which was formerly known as Anaconda® Distribution),
- Modify and create derivative works of sample source code delivered in Anaconda® Individual Edition from Anaconda’s repository; and
- Redistribute code files in source (if provided to you by Anaconda as source) and binary forms, with or without modification subject to the requirements set forth below.

Anaconda may, at its option, make available patches, workarounds or other updates to Anaconda® Individual Edition. Unless the updates are provided with their separate governing terms, they are deemed part of Anaconda® Individual Edition licensed to you as provided in this Agreement. This Agreement does not entitle you to any support for Anaconda® Individual Edition.

Anaconda reserves all rights not expressly granted to you in this Agreement.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

- Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
- Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
- Neither the name of Anaconda nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

You acknowledge that, as between you and Anaconda, Anaconda owns all right, title, and interest, including all intellectual property rights, in and to Anaconda® Individual Edition and, with respect to third-party products distributed with or through Anaconda® Individual Edition, the applicable third-party licensors own all right, title and interest, including all intellectual property rights, in and to such products. If you send or transmit any communications or materials to Anaconda suggesting or recommending changes to the software or documentation, including without limitation, new features or functionality relating thereto, or any comments, questions, suggestions or the like (“Feedback”), Anaconda is free to use such Feedback. You hereby assign to Anaconda all right, title, and interest in, and Anaconda is free to use, without any attribution or compensation to any party, any ideas, know-how, concepts, techniques or other intellectual property rights contained in the Feedback, for any purpose whatsoever, although Anaconda is not required to use any Feedback.

THIS SOFTWARE IS PROVIDED BY ANACONDA AND ITS CONTRIBUTORS “AS IS” AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL ANACONDA BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

TO THE MAXIMUM EXTENT PERMITTED BY LAW, ANACONDA AND ITS AFFILIATES SHALL NOT BE LIABLE FOR ANY SPECIAL, INCIDENTAL, PUNITIVE OR CONSEQUENTIAL DAMAGES, OR ANY LOST PROFITS, LOSS OF USE, LOSS OF DATA OR LOSS OF GOODWILL, OR THE COSTS OF PROCURING SUBSTITUTE PRODUCTS, ARISING OUT OF OR IN CONNECTION WITH THIS AGREEMENT OR THE USE OR PERFORMANCE OF ANACONDA® INDIVIDUAL EDITION, WHETHER SUCH LIABILITY ARISES FROM ANY CLAIM BASED UPON BREACH OF CONTRACT, BREACH OF WARRANTY, TORT (INCLUDING NEGLIGENCE), PRODUCT LIABILITY OR ANY OTHER CAUSE OF ACTION OR THEORY OF LIABILITY. IN NO EVENT WILL THE TOTAL CUMULATIVE LIABILITY OF ANACONDA AND ITS AFFILIATES UNDER OR ARISING OUT OF THIS AGREEMENT EXCEED US\$10.00.

If you want to terminate this Agreement, you may do so by discontinuing use of Anaconda® Individual Edition. Anaconda may, at any time, terminate this Agreement and the license granted hereunder if you fail to comply with any term of this Agreement. Upon any termination of this Agreement, you agree to promptly discontinue use of the Anaconda® Individual Edition and destroy all copies in your possession or control. Upon any termination of this Agreement all provisions survive except for the licenses granted to you.

This Agreement is governed by and construed in accordance with the internal laws of the State of Texas without giving effect to any choice or conflict of law provision or rule that would require or permit the application of the laws of any jurisdiction other than those of the State of Texas. Any legal suit, action, or proceeding arising out of or related to this Agreement or the licenses granted hereunder by you must be instituted exclusively in the federal courts of the United States or the courts of the State of Texas in each case located in Travis County, Texas, and you irrevocably submit to the jurisdiction of such courts in any such suit, action, or proceeding.

Notice of Third Party Software Licenses

Anaconda® Individual Edition provides access to a repository which contains software packages or tools licensed on an open source basis from third parties and binary packages of these third party tools. These third party software packages or tools are provided on an “as is” basis and are subject to their respective license agreements as well as this Agreement and the Terms of Service for the Repository located at <https://know.anaconda.com/TOS.html>. These licenses may be accessed from within the Anaconda® Individual Edition software or at <https://docs.anaconda.com/anaconda/pkg-docs>. Information regarding which license is applicable is available from within many of the third party software packages and tools and at <https://repo.anaconda.com/pkg/main/> and <https://repo.anaconda.com/pkg/r/>. Anaconda reserves the right, in its sole discretion, to change which third party tools are included in the repository accessible through Anaconda® Individual Edition.

Intel® Math Kernel Library

Anaconda® Individual Edition provides access re-distributable, run-time, shared-library files from the Intel® Math Kernel Library (“MKL binaries”).

Copyright © 2018 Intel Corporation. License available at <https://software.intel.com/en-us/license/intel-simplified-software-license> (the “MKL License”). You may use and redistribute the MKL binaries, without modification, provided the following conditions are met:

- Redistributions must reproduce the above copyright notice and the following terms of use in the MKL binaries and in the documentation and/or other materials provided with the distribution.
- Neither the name of Intel nor the names of its suppliers may be used to endorse or promote products derived from the MKL binaries without specific prior written permission.
- No reverse engineering, decompilation, or disassembly of the MKL binaries is permitted.

You are specifically authorized to use and redistribute the MKL binaries with your installation of Anaconda® Individual Edition subject to the terms set forth in the MKL License. You are also authorized to redistribute the MKL binaries with Anaconda® Individual Edition or in the Anaconda® package that contains the MKL binaries. If needed, instructions for removing the MKL binaries after installation of Anaconda® Individual Edition are available at <https://docs.anaconda.com>.

cuDNN Software

Anaconda® Individual Edition also provides access to cuDNN™ software binaries (“cuDNN binaries”) from NVIDIA® Corporation. You are specifically authorized to use the cuDNN binaries with your installation of Anaconda® Individual Edition subject to your compliance with the license agreement located at <https://docs.nvidia.com/deeplearning/sdk/cudnn-sla/index.html>. You are also authorized to redistribute the cuDNN binaries with an Anaconda® Individual Edition package that contains the cuDNN binaries. You can add or remove the cuDNN binaries utilizing the install and uninstall features in Anaconda® Individual Edition.

cuDNN binaries contain source code provided by NVIDIA Corporation.

Export; Cryptography Notice

You must comply with all domestic and international export laws and regulations that apply to the software, which include restrictions on destinations, end users, and end use. Anaconda® Individual Edition includes cryptographic software. The country in which you currently reside may have restrictions on the import, possession, use, and/or re-export to another country, of encryption software. BEFORE using any encryption software, please check your country’s laws, regulations and policies concerning the import, possession, or use, and re-export of encryption software, to see if this is permitted. See the Wassenaar Arrangement <http://www.wassenaar.org/> for more information.

Anaconda has self-classified this software as Export Commodity Control Number (ECCN) 5D992.c, which includes mass market information security software using or performing cryptographic functions with asymmetric algorithms. No license is required for export of this software to non-embargoed countries. The Intel® Math Kernel Library contained in Anaconda® Individual Edition is classified by Intel® as ECCN 5D992.c with no license required for export to non-embargoed countries.

The following packages are included in the repository accessible through Anaconda® Individual Edition that relate to cryptography:

- `openssl` The OpenSSL Project is a collaborative effort to develop a robust, commercial-grade, full-featured, and Open Source toolkit implementing the Transport Layer Security (TLS) and Secure Sockets Layer (SSL) protocols as well as a full-strength general purpose cryptography library.
- `pycrypto` A collection of both secure hash functions (such as SHA256 and RIPEMD160), and various encryption algorithms (AES, DES, RSA, ElGamal, etc.).
- `pyopenssl` A thin Python wrapper around (a subset of) the OpenSSL library.
- `kerberos` (krb5, non-Windows platforms) A network authentication protocol designed to provide strong authentication for client/server applications by using secret-key cryptography.
- `cryptography` A Python library which exposes cryptographic recipes and primitives.
- `pycryptodome` A fork of PyCrypto. It is a self-contained Python package of low-level cryptographic primitives. (<https://pycryptodome.readthedocs.io/en/latest/src/introduction.html>)
- `pycryptodomex` A stand-alone version of pycryptodome.
- `libsodium` A software library for encryption, decryption, signatures, password hashing and more.
- `pynacl` A Python binding to the Networking and Cryptography library, a crypto library with the stated goal of improving usability, security and speed.

4.3 Anaconda Cloud

What is Anaconda Cloud?

Anaconda Cloud is a package management service by **Anaconda**. Cloud makes it easy to find, access, store and share public notebooks, environments, and conda and PyPI packages. Cloud also makes it easy to stay current with updates made to the packages and environments you are using. Cloud hosts hundreds of useful Python packages, notebooks, projects and environments for a wide variety of applications. You do not need to log in, or even to have a Cloud account, to search for public packages, download and install them.

You can build new conda packages using `conda-build`, then upload the packages to Cloud to quickly share with others or access yourself from anywhere. The Anaconda Cloud command line interface (CLI), `anaconda-client`, allows you to manage your account - including authentication, tokens, upload, download, remove and search.

Connect to and manage your Anaconda Cloud account. Upload packages you have created. Generate access tokens to allow access to private packages.

For developers, Cloud is designed to make software development, release and maintenance easy by providing broad package management support. Cloud allows for free public package hosting, as well as package channels, providing a flexible and scalable service for groups and organizations of all sizes.

Hosting of freely available packages always remains free for individuals and organizations hosting up to 3 GB of packages.

To use Cloud, you should first:

- **Download Anaconda.** The Anaconda installer

includes `conda`, `conda-build` and `anaconda-client`.

- Become familiar with using conda. A good place to start is the [conda cheat sheet](#) and the [conda test drive](#).

4.3.1 User guide

Anaconda Cloud is a package management service that makes it easy to find, access, store and share public notebooks, environments, and conda and PyPI packages. Cloud also makes it easy to stay current with updates made to the

packages and environments you are using.

To begin using Cloud, read *Getting started*, then the remaining sections of the user guide.

Getting started

- *Installing Anaconda Client*
- *Finding, downloading and installing packages*
- *Building and uploading packages*
- *Sharing notebooks*
- *Sharing environments*

Installing Anaconda Client

You can use Anaconda Client command line interface (CLI) to:

- Connect to and manage your Anaconda Cloud account.
- Upload *packages* you have created.
- Generate access *tokens* to allow access to private packages.

NOTE: Client is not necessary to search for and download packages.

This tool can be installed using an Anaconda Prompt or the Terminal application in three ways: with `conda`, with `pip` or with `pip` from source. We recommend using `conda`.

Option 1, `conda`:

```
conda install anaconda-client
```

Option 2, `pip`:

```
pip install anaconda-client
```

Option 3, installing with `pip` from source:

```
pip install git+https://github.com/Anaconda-Platform/anaconda-client
```

After installing, view the complete list of Client tasks with this command:

```
anaconda -h
```

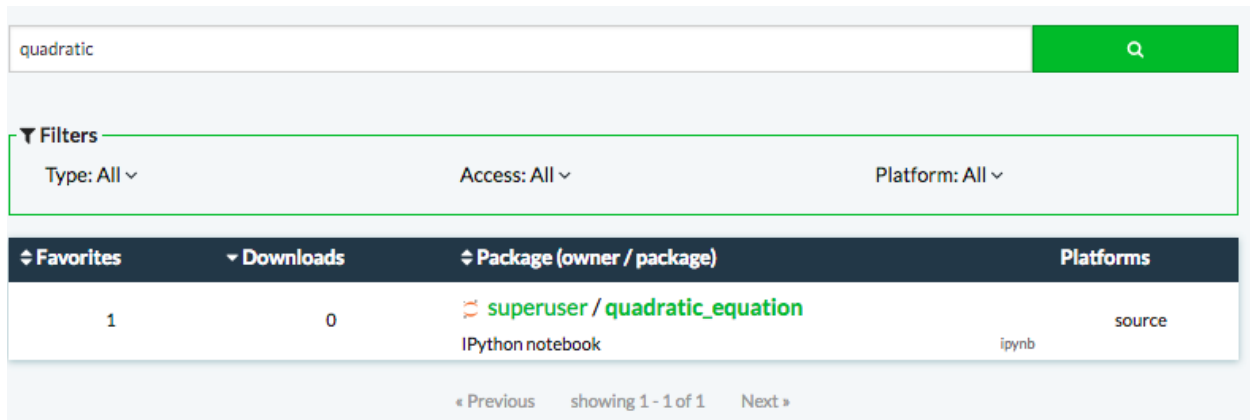

Finding, downloading and installing packages

Searching for public packages

`Cloud` hosts hundreds of useful Python packages for a wide variety of applications. You do not need to be logged in, or even need a Cloud account, to search for public packages, download and install them. You need an account only to access *private packages* without a *token* or to share your packages with others.

To search for packages:

1. In the top Search box, type part or all of the name of a program you are searching for, and then press Enter.
2. Packages that match your search string are displayed. To see more information, click the package name.

For more information, see [Working with packages](#).

Refining your search results

You can filter search results using 3 filter controls:

- **Type:** All, conda only or PyPI only.
- **Access:** All, Public and/or Private—only available if you are logged in.
- **Platform:** All, source, linux-32, linux-64, linux-armv61, linux-armv71, linux-ppc64le, noarch, osx-32, osx-64, win-32, win-64.

Source packages are source code only, not yet built for any specific platform.

Noarch packages are built to work on all platforms.

Downloading and installing packages from Cloud

You can download and install packages using [Anaconda Navigator](#), the graphical user interface for Anaconda. Advanced users may prefer a terminal window or command prompt.

Using Navigator

Navigator is automatically installed when you install Anaconda®.

To download and install a package into its own environment:

1. Start Navigator by clicking its program icon on your desktop or in your programs menu.
2. Sign Navigator into Cloud so you can search for packages marked as private. Click the top right Sign in to Anaconda Cloud button and type your Cloud username and password, then click the Login button.

3. On the **Environments** tab, in the far-right Search packages box, enter the name of the desired package.
4. In the list to the left of Channels, select either Not installed or All, then click the Search button.
5. Select the checkbox of the package you want to install, then click the Apply button.

For more information, see [Navigator](#).

Using conda in a Terminal window or Anaconda Prompt

To download and install a package into its own environment:

1. Locate a package on Cloud that you want to download, then click on the package name.
2. A detail page displays specific installation instructions for the current operating system. Copy and paste the full command into your terminal window.

For example, the command could be structured as:

```
conda install -c username packagename
```

NOTE: For the following examples to work, you need to have [conda](#) downloaded and installed.

TIP: Conda expands `username` to a URL such as <https://anaconda.org/username>, based on the settings in the `.condarc` file.

Building and uploading packages

[Open a Cloud account](#) to upload packages or to access private packages without a token.

To build and upload packages, install the Client command line interface (CLI). For more information, see [Installing Anaconda Client](#).

Use the Terminal window or an Anaconda Prompt to perform the following steps.

1. Install Anaconda Client:

```
conda install anaconda-client
```

2. Log into your Cloud account:

```
anaconda login
```

At the prompt, enter your Cloud username and password.

3. Choose the package you would like to build. For this example, download our public test package:

```
git clone https://github.com/Anaconda-Platform/anaconda-client
cd anaconda-client/example-packages/conda/
```

4. To build your test package, first install `conda-build` and turn off automatic Client uploading, then run the `conda build` command:

```
conda install conda-build
conda config --set anaconda_upload no
conda build .
```

5. Find the path to where the newly-built file was placed so you can use it in the next step:

```
conda build . --output
```

6. Upload your newly-built test package to your Cloud account:

```
anaconda login  
anaconda upload /your/path/conda-package.tar.bz2
```

NOTE: Replace `/your/path/` with the actual path that you found in the previous step.

For more information, see [conda packages](#).

Sharing notebooks

To share a [Jupyter notebook](#)—formerly IPython notebook—on Cloud:

1. To Upload your notebook to Cloud, open the Terminal or an Anaconda Prompt and enter:

```
anaconda upload my-notebook.ipynb
```

NOTE: Replace `my-notebook` with the actual name of your notebook.

2. You can see an HTML version of your notebook stored at:

```
http://notebooks.anaconda.org/<USERNAME>/my-notebook
```

NOTE: Replace `<USERNAME>` with your username, and `my-notebook` with the actual name of your notebook.

3. Anyone who has access to Cloud can download your notebook. To download the notebook, open the Terminal or an Anaconda Prompt and enter:

```
anaconda download username/my-notebook
```

NOTE: Replace `username` with your username, and `my-notebook` with the actual name of your notebook.

Sharing environments

To share an environment on Cloud:

1. See the [conda user guide](#) to create and save a conda environment. Open the Terminal or an Anaconda Prompt and enter:

```
conda env export -n my-environment -f my-environment.yml
```

NOTE: Replace `my-environment` with the actual name of your environment.

2. Upload it to Cloud either using the web interface or the `anaconda upload` command.

- Using the web interface:

Go to <https://anaconda.org/USERNAME/environments>.

NOTE: Replace `USERNAME` with your username.

In the top right corner use the Upload button to upload your environment.

- Using the `anaconda upload` command from the Terminal window or an Anaconda Prompt:

```
anaconda upload my-environment.yml
```

NOTE: Replace `my-environment` with the actual name of your environment.

3. You can see a list of your uploaded environments at:

```
http://envs.anaconda.org/<USERNAME>
```

NOTE: Replace `<USERNAME>` with your username.

4. Anyone can download and install your environment from Cloud.

- Using the web interface:

Go to `https://anaconda.org/USERNAME/environments`.

NOTE: Replace `USERNAME` with the username.

Select the environment, click the Files tab, and under the Names field click the file to download.

- Using the Terminal or an Anaconda Prompt:

```
conda env create user/my-environment
source activate my-environment
```

NOTE: Replace `my-environment` with the actual name of your environment.

How to...

- *Use packages*
- *Use the Anaconda Client CLI*
- *Build packages*

Use packages

Finding a package

In your browser, you can search Anaconda Cloud for packages by package name. From the top navigation bar of any page, enter the package name in the search box. You can filter your searches to specify only conda or PyPI packages, and you can sort results by number of favorites or number of downloads by clicking the search results column heading.

Downloading and installing a package from Cloud

To install a conda package, in your Terminal window or Anaconda Prompt run:

```
conda install -c username packagename
```

Conda expands `username` to a URL such as <https://anaconda.org/username> or <https://conda.anaconda.org/username> based on the settings in the `.condarc` file.

NOTE: Replace `username` with your username, and `packagename` with the actual name of the package.

Downloading and installing a PyPI package from Cloud

To install a PyPI package, in your Terminal window or Anaconda Prompt run:

```
pip install --index-url pypi.anaconda.org/USERNAME/simple packagename
```

NOTE: Replace USERNAME with your username, and packagename with the actual name of the package.

Use the Anaconda Client CLI

Installing Client

For installation and setup instructions, see *Install Anaconda Client*.

Finding my Client login credentials

Your credentials for Client are those you used to create an account on Cloud.

To get help:

1. Go to <https://anaconda.org>.
2. Select the **Sign In** tab.
3. Click either I forgot my password or I forgot my username.

Logging into Client

After you have downloaded and configured Client, open a Terminal window or an Anaconda Prompt and run:

```
anaconda login
```

Displaying a list of Client commands

From a Terminal window or an Anaconda Prompt, run:

```
anaconda --help
```

Finding out more about a Client command

From a Terminal window or an Anaconda Prompt, run:

```
anaconda COMMANDNAME -h
```

NOTE: Replace COMMANDNAME with the name of the command about which you want more information.

Listing all available Client configuration files

From a Terminal window or an Anaconda Prompt, run:

```
anaconda config --files
```

Listing all of your Client configuration variables

From a Terminal window or an Anaconda Prompt, run:

```
anaconda config --show
```

Finding out more about Client

You can learn more about Client using the help command, documentation or community support email group.

Build packages

Building and uploading a package

For a quick example, see *Building and uploading packages* in *Getting started*.

Testing a built package

In your Terminal window or Anaconda Prompt run:

```
conda create --use-local -n test PACKAGENAME
```

Specify the `--use-local` option.

NOTE: Replace PACKAGENAME with the actual name of the package.

Uploading a package to Cloud

In a Terminal window or Anaconda Prompt, run:

```
anaconda upload PACKAGENAME
```

NOTE: Replace PACKAGENAME with the actual name of the package.

Finding help for uploading packages

You can obtain a complete list of upload options, including:

- Package channel.
- Label.
- Availability to other users.

- Metadata.

To list the options, in a Terminal window or Anaconda Prompt run:

```
anaconda upload -h
```

Tutorial

Using labels in the development cycle

Anaconda Cloud *labels* can be used to facilitate a development cycle and organize the code that is in development, in testing and in production, without affecting non-development users. With labels you can upload a file to a specific label, so only users who put that label in the URL they search are able to find it.

Using Anaconda Client, *package* developers can create additional labels such as development `labels/dev`, test `labels/test` or other labels that are searched only if the user specifies the label. The following search examples use a *namespace* of `travis`:

- <https://anaconda.org/travis/labels/main> – the label searched by default.
- <https://anaconda.org/travis> – same as default label with `main` implicit.
- <https://anaconda.org/travis/labels/dev> – contains the packages in development.
- <https://anaconda.org/travis/labels/test> – contains packages ready to test.
- <https://anaconda.org/travis/labels/any-custom-label> – any label you want to use.

In this example, we show you how to use a `test` label, so that you can upload files without affecting your production-quality packages. Without a `--label` argument the default label is `main`.

Use the Terminal window or an Anaconda Prompt to perform the following steps:

1. Let us start with a conda package. If you do not have one, use our example conda package. Before you build the package, edit the version in the `meta.yaml` file in `anaconda-client/example-packages/conda/` to be `2.0`:

```
git clone https://github.com/Anaconda-Platform/anaconda-client/
cd anaconda-client/example-packages/conda/
nano meta.yaml # Bump version to 2.0
conda config --set anaconda_upload no
conda build .
```

2. Upload your test package to Cloud using the Client *upload* command.

Adding the `--label` option tells Cloud to make the upload visible only to users who specify that label:

```
anaconda upload /path/to/conda-package-2.0.tar.bz2 --label test
```

NOTE: Replace `/path/to/` with the actual path where you stored the package.

3. You now can see that even when you search conda `main`, you do not see the `2.0` version of the test package. This is because you need to tell conda to look for your new `test` label.
4. The `--override` argument tells conda not to use any channels in your `~/.condarc` file.

No `2.0` results:

```
conda search --override -c USERNAME conda-package
```

NOTE: Replace USERNAME with your username.

Your 2.0 package is here:

```
conda search --override -c USERNAME/label/test conda-package
```

NOTE: Replace USERNAME with your username.

5. You can give the label USERNAME/label/test to your testers.

NOTE: Replace USERNAME with your username.

6. Once they finish testing, you may then want to copy the test packages back to your main label:

```
anaconda label --copy test main
```

You can also manage your package labels from your dashboard: <https://anaconda.org/USERNAME/conda-package>.

Your version 2.0 is now in main:

```
conda search --override -c USERNAME conda-package
```

NOTE: Replace USERNAME with your username.

If you use `anaconda-client` 1.7 or higher, you can use `anaconda move` to move packages from one label to another:

```
anaconda move --from-label OLD --to-label NEW SPEC
```

Replace OLD with the old label, NEW with the new label, and SPEC with the package to move. SPEC can be either “user/package/version/file”, or “user/package/version” in which case it moves all files in that version.

Tasks

Working with accounts

- *Personal accounts*
- *Organization accounts*

Personal accounts

Overview

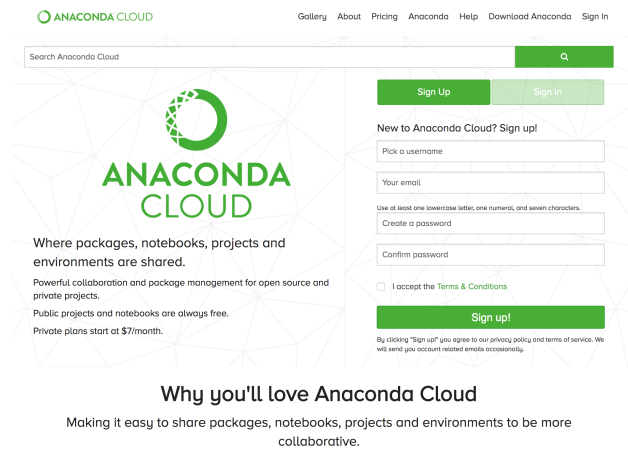

This section explains how to create a free, personal account, log in and out, and access the settings and features of different types of accounts.

Creating a free account

All Anaconda Cloud users can find, download and use packages without having a Cloud account.

However, you need to create a Cloud account to:

- Author packages.
- Upload packages, notebooks and environments.
- Access shared, private packages.
- Create organizations.

To sign up for a free Cloud account:

1. In a browser, go to [Anaconda Cloud](#).
2. Make sure the **Sign Up** tab is active.

NOTE: There is also a **Sign In** tab for existing users.

3. Select a username.
4. Enter your email address.

NOTE: Users who register with an .edu email are granted some additional features.

5. Create a password.
6. Enter the password again to confirm it.
7. Read and accept the Terms and Conditions.
8. Click the Sign up button.

The system creates your free account, logs you in and displays your personal dashboard.

TIP: Cloud displays your profile photo if the email address you used to register on Cloud is associated with a Gravatar account. To associate your email address or to change your Gravatar profile photo, go to [gravatar.com](#).

When you are logged into Cloud, the Profile list appears at the top right of every page. This indicates the name of the currently active user or organization.

The View menu contains these options:

- Landscape: Your home page.
- Favorites: Packages from other users you have starred.
- Packages: Only packages you have created.
- Notebooks: Only notebooks you have created.
- Environments: Only environments you have created.
- Projects: Only projects you have uploaded.

Packages, notebooks and environments that you have created with this account appear on your dashboard. For more information, see [packages](#).

Resetting your password

The **Sign In** tab provides two links to help regain access to your account:

- I forgot my username. Click this link to have the username emailed to the email address of record.
- I forgot my password. Click this link to have a reset password link sent to the email address of record.

NOTE: The reset password link expires within 24 hours. If you no longer have access to the email account, you can create a new account or email support@anaconda.com for assistance.

Upgrading or downgrading your plan

To change a Cloud plan:

1. Log in to the Cloud account that you want to change.
2. At the top right of the Cloud interface, in the Profile list, select Settings.
3. Select the Billing option.

4. Click the Change Plan button.
5. Select the desired plan.

If you are moving from a free to a charged plan, enter your credit card information, and then click the OK button.

NOTE: If you need more private packages or storage space than is included in a personal plan, [contact Anaconda](#) so we can customize a plan for you.

NOTE: If you need assistance with billing questions, you can [contact Anaconda](#).

Creating access tokens

The best way to manage access or make packages private is to create [organizations](#) or [groups](#), which allow you to set separate permissions per package, notebook or environment.

You can also control access with the [token](#) system. You can use tokens to control access to private repositories, collections or packages on Cloud. Additionally, the degree of access a token grants is completely configurable at the time of generation. You can generate multiple tokens to control which groups of users have access to certain features if they have the appropriate token.

Generating tokens

You can generate tokens using the Web UI or Anaconda Client.

NOTE: By default, tokens expire after one year.

To generate a token using the Web UI:

1. Navigate to:

```
https://anaconda.org/<channel>/settings/access
```

NOTE: Replace `<channel>` with the actual channel name.

2. From here you can select a name for the token and set the required scopes.

To generate a token with Client:

1. In your Terminal window or Anaconda Prompt run:

```
anaconda auth --create --name YOUR-TOKEN-NAME --scopes 'repos conda:download'
```

NOTE: Replace YOUR-TOKEN-NAME with the token name you want.

2. This generates a random alphanumeric token string, which you can then distribute to fellow Cloud users to enable them to download a package that you have marked private. The token produced in this example provides access to download any of your private conda repositories.
3. It can be enabled with the `conda config` command. In your Terminal window or Anaconda Prompt run:

```
conda config --add channels https://conda.anaconda.org/t/<token>/<channel>

Add a channel with a token and a label::

conda config --add channels https://conda.anaconda.org/t/<token>/<channel>/
↪label/<labelname>

NOTE: Replace ``<token>`` with your token string, ``<channel>`` with the channel_
↪name,
``<labelname>`` with the label name used in :ref:`cloud-accounts-generate`.
```

NOTE: If you lose the random alphanumeric string, you need to *revoke the token* and create a new one.

Scopes are provided as a space-separated, quoted list. The available scopes are:

- `all`: Allow all operations.
- `api`: Allow all API operations.
- `api:modify-group`: Allow addition and modification of groups.
- `api:read`: Allow read access to the API site.
- `api:write`: Allow write access to the API site.
- `conda`: Allow all operations on Conda repositories.
- `conda:download`: Allow private downloads from Conda repositories.

- `pypi`: Allow all operations on PyPI repositories.
- `pypi:download`: Allow private downloads from PyPI repositories.
- `pypi:upload`: Allow uploads to PyPI repositories.
- `repos`: Allow access to all package repositories.

NOTE: Tokens provide access to all packages within a specified channel. Separate permissions per package, notebook or environment may be better handled with *organizations* and *groups*.

Revoking tokens

You can revoke tokens using the Web UI or Anaconda Client.

To revoke a token using the Web UI, navigate to the following URL:

```
https://anaconda.org/<channel>/settings/access
```

NOTE: Replace `<channel>` with the actual channel name.

To revoke a token using Client, in your Terminal window or Anaconda Prompt run:

```
anaconda auth -r YOUR-TOKEN-NAME
```

NOTE: Replace `YOUR-TOKEN-NAME` with the token name you want to revoke.

Organization accounts

Overview

You can create a *Cloud organization* to:

- Share packages, environments or notebooks under an organization's account rather than your personal account.
- Assign multiple account administrators.
- Assign different access permissions to groups of users and customize per-package access by group.
- Host more, larger packages.

Working with organizations

- *Creating an organization*
- *Deleting an organization*
- *Customizing users and groups*
- *Uploading packages to an organization*
- *Creating groups for differing access levels*

Organizations enable you to maintain group-owned repositories and set access levels for various users in the group.

Creating an organization

To create an organization:

1. Log in to Anaconda Cloud.
2. In the Tools list, select Organizations, and then scroll to the bottom of the page.
3. Supply an organization name.

NOTE: Organization names cannot include spaces or special characters.

4. Supply an email address, then click the Create Organization button.

The system displays the dashboard for the new organization.

As the creator and owner of an organization, you have automatic administrative access to this organization and any packages associated with the organization.

In the Tools list, the Group Membership option shows a list of all organizations to which you belong.

Deleting an organization

To delete an organization you administer and erase all data associated with it:

1. At the top right of the Cloud interface, in the Profile list, select Switch To.
2. Select the organization you want to delete.
3. In the Profile list, select Settings.
4. Select the Account option. You may be asked to verify your password.
5. In the Delete Account section, click the Delete button.

A confirmation page then requests that you provide the full name of the organization.

Customizing users and groups

To add, remove, or edit group and user access for an organization you administer:

1. At the top right of the Cloud interface, in the Profile list, select the desired organization profile.
2. In the Tools list, select Groups.
3. You can review and edit the current group and user access for an organization, as well as add new groups and users at this address: <https://anaconda.org/<OrgName>/groups/>

NOTE: Replace <OrgName> with the organization name.

NOTE: Users receive a dashboard notification when you add them to an organization.

Uploading packages to an organization

To upload a package to an organization, use the `-u/--user` option and in the Terminal window or an Anaconda Prompt, run:

```
anaconda upload --user ORGANIZATION package.tar.bz2
```

NOTE: Replace `ORGANIZATION` with the organization name, and `package.tar.bz2` with the actual name of the package.

NOTE: Only the co-owners of an organization may upload packages to the organization.

Creating groups for differing access levels

Within an organization, you can create a group to customize access for a group of users. There are four types of permissions you can grant:

- **Read:** Provides access only to the packages. Users in a read-only group can see the list of files within a package and can install them through conda.
- **Read-Write:** Provides access to upload new versions of an existing package, delete files of a package and manage the individual labels of files. Users in a read-write group cannot upload files for non-existing packages, cannot delete or transfer the package and cannot lock and unlock labels.
- **Admin:** Provides access do everything except uploading new packages (admin users can still upload to an existing package) and lock and unlock labels.
- **Owners:** The user has full control over the organization and group.

To create a group and set access levels:

1. Click the +New Group button.
2. Give the group a name, and assign the desired permissions– Read-Only, Read-Write or Administration.
3. Add the desired members by username in the Members box.
4. Add the packages which this group can access in the Packages box.
5. Click the Save Group button.

Working with packages

- *Overview*
- *Using package managers*
- *Uploading packages*
- *Using private packages*
- *Removing a previous version of a package*
- *Adding a collaborator to a package*
- *Removing a collaborator from a package*
- *Transferring a package to a new owner*
- *Copying a package*
- *Deleting a package*

Overview

All files uploaded to Anaconda Cloud are stored in packages. Each Cloud package is visible at its own unique URL based on the name of the user who owns the package and the name of the package.

Users can create a Cloud package and then upload files into it.

For more information, see *package*.

Note: Throughout this task, replace placeholder text like `USERNAME` and `PACKAGENAME` with the text specific to your project.

Namespaces

A namespace is the part of Cloud where a user or organization may host packages. For example, the user namespace <https://anaconda.org/travis> contains packages that were uploaded and shared by a user named `travis`.

For more information, see *namespace*.

Labels

A label is part of the URLs on Cloud where conda looks for packages.

Each file within a package may be tagged with one or more labels, or not tagged at all to accept the default label of `main`.

For more information, see *label*.

Using package managers

Cloud supports two package managers, *conda* and *PyPI*. To work with conda or PyPI packages, you must use their corresponding subdomains:

- To install conda packages from the user `travis`, use the repository URL `https://conda.anaconda.org/travis`
- To install PyPI packages from the user `travis`, use the repository URL `https://pypi.anaconda.org/travis`

Conda packages

Uploading conda packages

This example shows how to build and upload a *conda* package to Cloud using `conda build`.

Use the terminal window or an Anaconda Prompt to perform the following steps:

1. Before you start, install `anaconda-client` and `conda-build`:

```
conda install anaconda-client conda-build
```

2. Choose the repository for which you would like to build the package. In this example, we use a simple public *conda test* package:

```
git clone https://github.com/Anaconda-Platform/anaconda-client
cd anaconda-client/example-packages/conda/
```

In this directory, there are two required files, `meta.yaml` and `build.sh`.

macOS and Linux systems are Unix systems. Packages built for Unix systems require a `build.sh` file, packages built for Windows require a `bld.bat` file, and packages built for both Windows and Unix systems require both a `build.sh` file and a `bld.bat` file. All packages require a `meta.yaml` file.

3. To build the package, turn off automatic Client uploading and then run the `conda build` command:

```
conda config --set anaconda_upload no
conda build .
```

All packages built in this way are placed in a subdirectory of the *Anaconda* `conda-bld` directory.

4. You can check where the resulting file was placed with the `--output` option:

```
conda build . --output
```

5. You can upload the test package to Cloud with the Anaconda *upload* command:

```
anaconda login
anaconda upload /path/to/conda-package.tar.bz2
```

Note: Replace `/path/to/` with the actual path where you stored the package.

For more information on conda's overall build framework, you may also want to read the articles [Building conda packages](#).

Installing conda packages

You can install conda packages from Cloud by adding channels to your conda configuration.

Use the terminal window or an Anaconda Prompt to perform the following steps:

1. Because conda knows how to interact with Cloud, specifying the channel `sean` translates to <https://anaconda.org/sean>:

```
conda config --add channels sean
```

2. You can now install public conda packages from Sean's Cloud account. Try installing the `testci` package at <https://anaconda.org/sean/testci>:

```
conda install testci
```

3. You can install a package from a channel with a token and a label:

```
conda install -c https://conda.anaconda.org/t/token/channel/label/labelname_
↪packagename
```

Note: Replace `token` with the provided token, `channel` with a user channel, `labelname` with the label name and `packagename` with the package name you want to install.

PyPI packages

Uploading PyPI packages

We can test PyPI package uploading with a small public example package saved in the [anaconda-client repository](#).

Use the terminal window or an Anaconda Prompt to perform the following steps:

1. Begin by cloning the repository from the command line:

```
git clone git@github.com:Anaconda-Platform/anaconda-client.git
cd anaconda-client/example-packages/pypi/
```

2. You can now create your PyPI package with the `setup.py` script:

```
python setup.py sdist
```

3. The package has now been built as a source tarball and is ready to be uploaded:

```
anaconda upload dist/*.tar.gz
```

Your package is now available at `http://anaconda.org/USERNAME/PACKAGE`.

Installing PyPI packages

The best way to install a PyPI package is using `pip`. For the following command, we use the package we authored in the examples above. In your terminal window or an Anaconda Prompt, run:

```
pip install --extra-index-url https://pypi.anaconda.org/USERNAME/simple pypi-test-  
↪package
```

Installing private PyPI packages

The best way to manage access or make PyPI and other packages private is to create [organizations](#) or [groups](#), which allow you to set separate permissions per package, notebook or environment.

You can also control access with the token system. All Cloud URLs can be prefixed with `/t/$TOKEN` to access private packages.

In your terminal window or an Anaconda Prompt, run:

```
TOKEN=$(anaconda auth --create --name YOUR-TOKEN-NAME)
pip install --index-url https://pypi.anaconda.org/t/$TOKEN/USERNAME/simple-test-  
↪package
```

Note: Replace `YOUR-TOKEN-NAME` with the name of the token you created, `USERNAME` with your username and `simple-test-package` with the actual test-package name.

Uploading packages

1. To upload package files to Cloud, use the terminal window or an Anaconda Prompt and the [upload](#) command:

```
anaconda login
anaconda upload PACKAGENAME
```

Cloud automatically detects packages and notebooks, package or notebook types, and their versions.

2. Your package is now available at:

```
https://anaconda.org/USERNAME/PACKAGENAME
```

3. Your package also can be downloaded by anyone using Client from the terminal window or an Anaconda Prompt:

```
anaconda download USERNAME/PACKAGENAME
```

Using private packages

It is no longer possible to sign up for an individual paid plan with private packages. Anyone who had private packages in the past still has the ability to have those hosted privately.

By default, all packages, notebooks, and environments uploaded to Cloud are accessible to anyone who has access to the repository.

Packages uploaded to your user channel on Cloud can be marked as private using the Web UI:

1. Select the desired package.
2. Select the **Settings** tab.
3. Select Admin in the sidebar.
4. Alternatively, you can reach this page with the following URL:

```
https://anaconda.org/username/packageName/settings/admin
```

Note: Jupyter notebooks and conda environments can also be marked private using this procedure and URL.

Note: Other Cloud users may access your private packages either with tokens or by logging in.

Private packages with tokens

Note: Replace `token` with the provided token, `channel` with a user channel, `labelname` with the label name, and `packagename` with a package name you want to install.

To make your private packages available to be accessed with tokens:

1. First create an access *token* that includes the following scope for Client:

```
conda:download
```

Or, in the Web UI with:

```
Allow private downloads from conda repositories
```

The token is a random alphanumeric string and this is used to install a package or add a channel from which you want to install private packages.

2. Using the provided token, a user channel can be added to `config` from the terminal window or an Anaconda Prompt with:

```
conda config --add channels https://conda.anaconda.org/t/token/channel
```

3. The token can also be used to install packages without first adding the channel. In the terminal window or an Anaconda Prompt, run:

```
conda install -c https://conda.anaconda.org/t/token/channel packagename
```

To install a package from a channel using token and label name:

```
conda install -c https://conda.anaconda.org/t/token/channel/label/labelname_↵  
↵packagename
```

4. Private PyPI packages can also be installed in the Web UI:

```
https://pypi.anaconda.org/t/token/channel
```

Private packages with login

To make your private packages available to users who have logged in:

1. Create an *organization*.
2. Create a group in that organization, which may be a read-only group.
3. Add to the group the users that you want to grant access to.
4. Upload the package to the organization, or transfer an existing package to the organization.

After you grant them access, other users can download and install your package using the Web UI or Client.

To download a package:

1. In a browser, navigate to the desired channel.
2. If the organization name is `OrgName` and the package name is `conda-package`, use these commands in the terminal window or an Anaconda Prompt:

```
conda install anaconda-client  
anaconda login  
conda install -c OrgName conda-package
```

Or instead:

```
conda install anaconda-client  
anaconda login  
conda install -c https://conda.anaconda.org/OrgName conda-package
```

Removing a previous version of a package

To remove a previous version of one of your packages from Cloud:

1. Select the package name.
2. Select the **Files** tab.
3. Select the checkbox to the left of the version you want to remove.
4. In the **Actions** menu, select Remove.

You may instead use the terminal window or an Anaconda Prompt:

1. Run:

```
anaconda remove USERNAME/PACKAGENAME/0.2
```

Note: Replace USERNAME with your username, PACKAGENAME with the package name and 0.2 with the desired version.

2. You can now see the change on your profile page:

```
https://anaconda.org/USERNAME/PACKAGE
```

Adding a collaborator to a package

You can add other users that are not part of an organization to collaborate on your packages. You will need the usernames of the other users.

1. From your dashboard, select the package by clicking on its name.
2. To display the package settings, select the Settings option.
3. To display the current collaborators, select the Collaborators option.
4. Type the username of the person you want to add as a collaborator, and then click the Add button.

Note: All collaborators are given full read/write permissions to the package, even private packages.

Removing a collaborator from a package

To revoke package access previously granted to a collaborator:

1. From your dashboard select the package by clicking on its name.
2. To display the package settings, select the Settings option.
3. To display the current collaborators, select the Collaborators option.
4. Click the red X button next to a collaborator to revoke their access.

Transferring a package to a new owner

By default, when you create or add packages, they are attached to your individual profile. You can transfer ownership to another owner account you control, such as an organization profile you manage.

To transfer a package to a new owner:

1. From your dashboard—or the dashboard of an organization you administer—select the package for which you want to transfer ownership.
The system displays options for that package.
2. To display the package settings, select the Settings option.
3. Select the Admin option.
4. Under Transfer this package to a new owner, click the Transfer button.
5. Select the organization name for the new owner.
6. Click the Transfer Ownership button.

Copying a package

To copy a package from the channel `conda-forge` to a personal channel such as `jsmith`:

```
anaconda copy conda-forge/glueviz/0.10.4 --to-owner jsmith
```

`conda-forge/glueviz/0.10.4` is a “spec” and can match either of two formats: `user/package/version` or `user/package/version/filename`.

Previously labels were called “channels”, and the `anaconda copy` command has deprecated options `from-channel` and `to-channel` that expect to operate on labels. These deprecated options should not be used. If you attempt to run `anaconda copy --from-channel conda-forge --to-channel jsmith glueviz`, you will receive an error that Label `conda-forge` does not exist.

Deleting a package

To delete a package from Cloud, including all of its versions:

1. Select the package name.
2. Select the Settings option.
3. In the left sidebar, select Admin.
4. Click Delete.

You may instead use the terminal window or an Anaconda Prompt:

1. Run:

```
anaconda remove USERNAME/PACKAGENAME
```

2. You can now see the change on your profile page:

```
https://anaconda.org/USERNAME
```

Working with notebooks

To begin working with Jupyter Notebooks, see the [Official Jupyter Notebook documentation](#).

To share a [Jupyter notebook](#) on Cloud:

1. Save a notebook.
2. Download and check out the handy JupyterLab and Jupyter Notebook cheat sheet to create and save a notebook.
3. To upload your notebook to Cloud, open Anaconda Prompt or Terminal and enter:

```
anaconda upload my-notebook.ipynb
```

NOTE: Replace `my-notebook` with the actual name of your notebook.

4. You can see an HTML version of your notebook stored at:

```
http://notebooks.anaconda.org/<USERNAME>/my-notebook
```

NOTE: Replace `<USERNAME>` with your username, and `my-notebook` with the actual name of your notebook.

5. Anyone who has access to Cloud can download your notebook. To download the notebook, open Anaconda Prompt or Terminal and enter:

```
anaconda download username/my-notebook
```

NOTE: Replace `username` with your username, and `my-notebook` with the actual name of your notebook.

Working with environments

To share an environment on Anaconda Cloud:

1. See the [conda user guide](#) to create and save a conda environment. Open the Terminal or an Anaconda Prompt and enter:

```
conda env export -n my-environment -f my-environment.yml
```

NOTE: Replace `my-environment` with the actual name of your environment.

2. Upload it to Cloud either using the web interface or the `anaconda upload` command.

- Using the web interface:

Go to <https://anaconda.org/USERNAME/environments>.

NOTE: Replace `USERNAME` with your username.

In the top right corner use the Upload button to upload your environment.

- Using the `anaconda upload` command from the Terminal or an Anaconda Prompt:

```
anaconda upload my-environment.yml
```

NOTE: Replace `my-environment` with the actual name of your environment.

3. You can see a list of your uploaded environments at:

```
http://envs.anaconda.org/USERNAME
```

NOTE: Replace USERNAME with your username.

4. Anyone can download and install your environment from Cloud.

- Using the web interface:

Go to `https://anaconda.org/USERNAME/environments`.

NOTE: Replace USERNAME with the username.

Select the environment, go to Files tab and click the file to download under Names field.

- Using the Terminal or an Anaconda Prompt:

```
conda env create user/my-environment
source activate my-environment
```

NOTE: Replace my-environment with the actual name of your environment.

Working with other file types

In addition to packages and notebooks, Anaconda Cloud can be used to store and share data science files of any type.

Uploading other file types

You can upload any type of file with the Anaconda Client command line interface (CLI) by using the steps below.

PyPI package files, conda package files and notebook files are automatically detected. There is no auto-detect for other types of files, so you must explicitly specify the package, package-type and version fields.

In the following example, we upload a spreadsheet named baby-names in comma separated value (CSV) format.

Use the Terminal window or an Anaconda Prompt to upload the spreadsheet:

1. Create a new package, which creates a *namespace* that can hold multiple files:

```
anaconda login
anaconda package --create jsmith/baby-names
```

2. Upload the file to the new namespace:

```
anaconda upload --user jsmith --package baby-names --package-type file --version 1
↪ 1 baby-names1.csv
```

NOTE: In this example, the user-or organization-name is jsmith, the package name is baby-names, the package type is file, the version is 1 and the full filename is baby-names1.csv.

Downloading other file types

Files, such as the one created above, are available at:

```
https://anaconda.org/<USERNAME>/<PACKAGENAME>
```

Anyone can download these files using Client from the Terminal window or an Anaconda Prompt:

```
anaconda download <USERNAME>/<PACKAGENAME>
```

NOTE: Replace `<USERNAME>` with the desired username, and `<PACKAGENAME>` with the desired package name.

If the repository has multiple files with the same name and different extensions, `anaconda download` will download all of them by default. If you use `anaconda-client` 1.7 or higher, you can use `anaconda download` with the option `--package-type` or `-t` to specify only one of these files. This option can work with the values `pypi`, `conda`, `ipynb`, and `env`.

4.3.2 FAQs

- *What is Anaconda Cloud?*
- *What kind of packages does Cloud support?*
- *Who can find and install my packages?*
- *What is Anaconda, Inc.?*
- *What are Cloud's terms of service?*
- *How much does Cloud cost?*
- *How do I get started with Cloud?*
- *What kind of account do I have?*
- *What is included in the free version of Cloud?*
- *What is an organization account, and how is it different from an individual account?*

What is Anaconda Cloud?

Anaconda Cloud is a package management service by [Anaconda](#). For more information, see [Anaconda Cloud](#).

What kind of packages does Cloud support?

Cloud supports any type of package. Today, it is primarily used for conda and PyPI packages, as well as notebooks and environments.

Who can find and install my packages?

If you have a free account, all of your packages are public. After you upload them to Cloud, anyone can search for and download them.

What is Anaconda, Inc.?

Anaconda is a software development and consulting company of passionate open source advocates based in Austin, Texas, USA. We are committed to the open source community. We created the Anaconda Python distribution and contribute to many other open source-based data analytics tools. You can find out more about us by reading [our story](#).

What are Cloud's terms of service?

Our terms of service are available at <https://anaconda.org/about/legal/terms> . For any additional questions, contact us by [email](#).

How much does Cloud cost?

Cloud is free for downloading and uploading public packages.

How do I get started with Cloud?

You can search, download and install hundreds of public packages without having an account. If you want to upload packages, you need to sign up for a [Cloud account](#). For more information, see [sign up for a free Cloud account](#).

What kind of account do I have?

By default your account is a personal, free account. All packages you upload to Cloud are public, and you are the only person with administrative access to your account.

What is included in the free version of Cloud?

The free plan allows you to search for, create and host public packages, and provides up to 3 GB storage space.

What is an organization account, and how is it different from an individual account?

An organization account allows multiple individual users to administer packages and have more control of package access by other users. An individual account is for use by one person.

4.3.3 Help and support

Joining community support

We invite you to join our community support mailing lists for both [Anaconda](#) and [conda](#). On these lists you can ask questions, answer questions and discuss ways to use Cloud. You also can submit requests for new features and make any other comments you may have.

Reporting a bug

Please use the Anaconda Cloud page [Report a Bug](#) to find the correct point of contact to report the bug you are experiencing. When reporting bugs on GitHub, please search to see if anyone else has reported it, and make a new issue if no one else has.

4.3.4 Command Reference

See also: [API Reference](#)

Anaconda client is the command line interface (CLI) to Anaconda Cloud, and can be used for logging in, logging out, managing your account, uploading files, generating access tokens, viewing tokens, and other tasks as shown by running:

```
anaconda -h
```

Full command reference:

anaconda

```
usage: anaconda [-h] [--disable-ssl-warnings] [--show-traceback] [-v] [-q]
               [-V] [-t TOKEN] [-s SITE]
               ...

Anaconda Cloud command line manager

optional arguments:
  -h, --help            show this help message and exit
  -V, --version          show program's version number and exit

output:
  --disable-ssl-warnings  Disable SSL warnings (default: False)
  --show-traceback       Show the full traceback for chalmers user errors
                        (default: False)
  -v, --verbose          print debug information ot the console
  -q, --quiet            Only show warnings or errors the console

anaconda-client options:
  -t TOKEN, --token TOKEN
                        Authentication token to use. May be a token or a path
                        to a file containing a token
  -s SITE, --site SITE  select the anaconda-client site to use

Commands:

  auth                Manage Authorization Tokens
  label               Manage your Anaconda Cloud labels
  channel              [DEPRECATED in favor of label] Manage your Anaconda
                        Cloud channels
  config              Anaconda client configuration
  copy                Copy packages from one account to another
  download             Download notebooks from Anaconda Cloud
  groups              Manage Groups
  login               Authenticate a user
  logout              Log out from Anaconda Cloud
  notebook             [DEPRECATED in favor of upload/download] Interact
                        with notebooks in anaconda.org
  package              Package utils
  remove              Remove an object from Anaconda Cloud. Must refer to
                        the formal package name as it appears in the URL of
                        the package. Also use anaconda show <USERNAME> to see
                        list of package names. Example: anaconda remove
                        continuumio/empty-example-notebook
  search              Search Anaconda Cloud
  show                Show information about an object
  upload              Upload packages to Anaconda Cloud
  whoami              Print the information of the current user
  build               Anaconda build client for continuous integration,
                        testing and building packages
```

(continues on next page)

(continued from previous page)

worker	Anaconda build client for continuous integration, testing and building packages
--------	---

Authentication

auth

```
usage: anaconda auth [-h] [-n NAME] [-o ORGANIZATION]
                    [--strength {strong,weak}] [--strong] [-w] [--url URL]
                    [--max-age MAX_AGE] [-s SCOPES] [--out OUT]
                    (-x | -l | -r NAME [NAME ...] | -c | -i)
```

Manage Authorization Tokens

optional arguments:

```
-h, --help            show this help message and exit
-n NAME, --name NAME  A unique name so you can identify this token later.
                     View your tokens at anaconda.org/settings/access
-o ORGANIZATION, --org ORGANIZATION, --organization ORGANIZATION
                     Set the token owner (must be an organization)
```

token creation arguments:

These arguments are only valid with the `--create` action

```
--strength {strong,weak}
--strong            Create a longer token (default)
-w, --weak          Create a shorter token
--url URL           The url of the application that will use this token
--max-age MAX_AGE   The maximum age in seconds that this token will be
                    valid for
-s SCOPES, --scopes SCOPES
                    Scopes for token. For example if you want to limit
                    this token to conda downloads only you would use
                    --scopes "repo conda:download"
--out OUT
```

actions:

```
-x, --list-scopes    list all authentication scopes
-l, --list           list all user authentication tokens
-r NAME [NAME ...], --remove NAME [NAME ...]
                    remove authentication tokens
-c, --create         Create an authentication token
-i, --info, --current-info
                    Show information about the current authentication
                    token
```

Manage Authentication tokens

See also: *Using Anaconda Cloud Tokens*

login

```
usage: anaconda login [-h] [--hostname HOSTNAME] [--username LOGIN_USERNAME]
                    [--password LOGIN_PASSWORD]

Authenticate a user

optional arguments:
  -h, --help            show this help message and exit
  --hostname HOSTNAME   Specify the host name of this login, this should be
                        unique (default: hq-phone-114.corp.continuum.io)
  --username LOGIN_USERNAME
                        Specify your username. If this is not given, you will
                        be prompted
  --password LOGIN_PASSWORD
                        Specify your password. If this is not given, you will
                        be prompted
```

logout

```
usage: anaconda logout [-h]

Log out from Anaconda Cloud

optional arguments:
  -h, --help  show this help message and exit
```

whoami

Print the information of the current user

```
usage: anaconda whoami [-h]

Print the information of the current user

optional arguments:
  -h, --help  show this help message and exit
```

Informational

show

```
usage: anaconda show [-h] spec

Show information about an object

positional arguments:
  spec          Package written as USER[/PACKAGE[/VERSION[/FILE]]]

optional arguments:
  -h, --help  show this help message and exit
```

(continues on next page)

(continued from previous page)

Show information about an `object`

Examples:

```
anaconda show continuumio
anaconda show continuumio/python
anaconda show continuumio/python/2.7.5
anaconda show sean/meta/1.2.0/meta.tar.gz
```

search

```
usage: anaconda search [-h] [-t {conda,pypi}]
                        [-p {osx-32,osx-64,win-32,win-64,linux-32,linux-64,linux-
↳ armv61,linux-armv71,linux-ppc64le,noarch}]
                        name
```

Search Anaconda Cloud

positional arguments:

name Search string

optional arguments:

```
-h, --help                      show this help message and exit
-t {conda,pypi}, --package-type {conda,pypi}
                                only search for packages of this type
-p {osx-32,osx-64,win-32,win-64,linux-32,linux-64,linux-armv61,linux-armv71,linux-
↳ ppc64le,noarch}, --platform {osx-32,osx-64,win-32,win-64,linux-32,linux-64,linux-
↳ armv61,linux-armv71,linux-ppc64le,noarch}
                                only search for packages of the chosen platform
```

Search Anaconda Cloud **for** packages

config

```
usage: anaconda config [-h] [--type TYPE] [--set name value] [--get name]
                        [--remove REMOVE] [--show] [-f] [--show-sources] [-u]
                        [-s]
```

Anaconda client configuration

optional arguments:

```
-h, --help                      show this help message and exit
--type TYPE                    The type of the values in the set commands
```

actions:

```
--set name value               sets a new variable: name value
--get name                      get value: name
--remove REMOVE                removes a variable
--show                          show all variables
-f, --files                    show the config file names
--show-sources                Display all identified config sources
```

(continues on next page)

(continued from previous page)

```

location:
    -u, --user           set a variable for this user
    -s, --system, --site set a variable for all users on this machine

anaconda-client configuration

Get, Set, Remove or Show the anaconda-client configuration.

##### anaconda-client sites

anaconda-client sites are a mechanism to allow users to quickly switch
between Anaconda Cloud instances. This is primarily used for testing
the anaconda alpha site. But also has applications for the
on-site [Anaconda Enterprise] (http://continuum.io/anaconda-server).

anaconda-client comes with two pre-configured sites `alpha` and
`binstar` you may use these in one of two ways:

    * Invoke the anaconda command with the `-s/--site` option
      e.g. to use the alpha testing site:

          anaconda -s alpha whoami

    * Set a site as the default:

          anaconda config --set default_site alpha
          anaconda whoami

##### Add an anaconda-client site

After installing Anaconda Enterprise
you can add a site named site_name like this:

    anaconda config --set sites.site_name.url "http://<anaconda-enterprise-ip>:<port>/
↪api"
    anaconda config --set default_site site_name

##### Site Options VS Global Options

All options can be set as global options - affecting all sites,
or site options - affecting only one site

By default options are set globally e.g.:

    anaconda config --set OPTION VALUE

If you want the option to be limited to a single site,
prefix the option with `sites.site_name` e.g.

    anaconda config --set sites.site_name.OPTION VALUE

##### Common anaconda-client configuration options

    * `url`: Set the anaconda api url (default: https://api.anaconda.org)
    * `ssl_verify`: Perform ssl validation on the https requests.
      ssl_verify may be `True`, `False` or a path to a root CA pem file.

```

(continues on next page)

(continued from previous page)

```
##### Toggle auto_register when doing anaconda upload

The default is yes, automatically create a new package when uploading.
If no, then an upload will fail if the package name does not already exist on the_
↪server.

anaconda config --set auto_register yes|no
```

Managing Packages

package

```
usage: anaconda package [-h]
                        (--add-collaborator user | --list-collaborators | --create)
                        [--summary SUMMARY] [--license LICENSE]
                        [--license-url LICENSE_URL] [--personal | --private]
                        USER/PACKAGE

Anaconda Cloud package utilities

positional arguments:
  USER/PACKAGE          Package to operate on

optional arguments:
  -h, --help            show this help message and exit

actions:
  --add-collaborator user
                        username of the collaborator you want to add
  --list-collaborators list all of the collaborators in a package
  --create              Create a package

metadata arguments:
  --summary SUMMARY    Set the package short summary
  --license LICENSE    Set the package license
  --license-url LICENSE_URL
                        Set the package license url

privacy:
  --personal           Set the package access to personal This package will
                        be available only on your personal registries
  --private            Set the package access to private This package will
                        require authorized and authenticated access to install
```

upload

```
usage: anaconda upload [-h] [-c CHANNELS] [-l LABELS] [--no-progress]
                        [-u USER] [--all] [-p PACKAGE] [-v VERSION]
                        [-s SUMMARY] [-t PACKAGE_TYPE] [-d DESCRIPTION]
                        [--thumbnail THUMBNAIL] [--private]
                        [--no-register | --register] [--build-id BUILD_ID]
```

(continues on next page)

(continued from previous page)

```

        [-i | -f | --force]
        files [files ...]

Upload packages to Anaconda Cloud

positional arguments:
  files                Distributions to upload

optional arguments:
  -h, --help            show this help message and exit
  -c CHANNELS, --channel CHANNELS
                        [DEPRECATED] Add this file to a specific channel.
                        Warning: if the file channels do not include "main",
                        the file will not show up in your user channel
  -l LABELS, --label LABELS
                        Add this file to a specific label. Warning: if the
                        file labels do not include "main", the file will not
                        show up in your user label
  --no-progress          Don't show upload progress
  -u USER, --user USER  User account or Organization, defaults to the current
                        user
  --all                  Use conda convert to generate packages for all
                        platforms and upload them
  --no-register          Don't create a new package namespace if it does not
                        exist
  --register             Create a new package namespace if it does not exist
  --build-id BUILD_ID    Anaconda Cloud Build ID (internal only)
  -i, --interactive      Run an interactive prompt if any packages are missing
  -f, --fail             Fail if a package or release does not exist (default)
  --force               Force a package upload regardless of errors

metadata options:
  -p PACKAGE, --package PACKAGE
                        Defaults to the package name in the uploaded file
  -v VERSION, --version VERSION
                        Defaults to the package version in the uploaded file
  -s SUMMARY, --summary SUMMARY
                        Set the summary of the package
  -t PACKAGE_TYPE, --package-type PACKAGE_TYPE
                        Set the package type [ipynb, env]. Defaults to
                        autodetect
  -d DESCRIPTION, --description DESCRIPTION
                        description of the file(s)
  --thumbnail THUMBNAIL
                        Notebook's thumbnail image
  --private             Create the package with private access

  anaconda upload CONDA_PACKAGE_1.bz2
  anaconda upload notebook.ipynb
  anaconda upload environment.yml

```

See Also:

- [Uploading a Conda Package](#)
- [Uploading a PyPI Package](#)

download

```
usage: anaconda download [-h] [-f] [-o OUTPUT] handle

Download packages from Anaconda Cloud

positional arguments:
  handle                user/notebook

optional arguments:
  -h, --help            show this help message and exit
  -f, --force           Overwrite
  -o OUTPUT, --output OUTPUT
                        Download as

Usage:
  anaconda download notebook
  anaconda download user/notebook
```

remove

```
usage: anaconda remove [-h] [-f] specs [specs ...]

Remove an object from Anaconda Cloud

example::

    anaconda remove sean/meta/1.2.0/meta.tar.gz

positional arguments:
  specs                Package written as <user>[/<package>[/<version>[/<filename>]]]

optional arguments:
  -h, --help          show this help message and exit
  -f, --force         Do not prompt removal
```

groups

```
usage: anaconda groups [-h] [--perms {read,write,admin}]
                        {add,show,members,add_member,remove_member,packages,add_
↪package,remove_package}
                        spec

positional arguments:
  {add,show,members,add_member,remove_member,packages,add_package,remove_package}
                        The group management command to execute
  spec                  <organization>/<group_name>/<member>

optional arguments:
  -h, --help            show this help message and exit
  --perms {read,write,admin}
                        The permission the group should provide
```

label

```
usage: anaconda label [-h] [-o ORGANIZATION]
                        (--copy LABEL LABEL | --list | --show LABEL | --lock LABEL | --
->unlock LABEL | --remove LABEL)
```

Manage your Anaconda Cloud channels

optional arguments:

```
-h, --help            show this help message and exit
-o ORGANIZATION, --organization ORGANIZATION
                        Manage an organizations labels
--copy LABEL LABEL
--list                list all labels for a user
--show LABEL          Show all of the files in a label
--lock LABEL          Lock a label
--unlock LABEL        Unlock a label
--remove LABEL        Remove a label
```

copy

```
usage: anaconda copy [-h] [--to-owner TO_OWNER] [--from-label FROM_LABEL]
                    [--to-label TO_LABEL]
                    spec
```

Copy packages from one account to another

positional arguments:

```
spec                Package - written as user/package/version[/filename]
                    If filename is not given, copy all files in the
                    version
```

optional arguments:

```
-h, --help            show this help message and exit
--to-owner TO_OWNER   User account to copy package to (default: your
                        account)
--from-label FROM_LABEL
                        Label to copy packages from
--to-label TO_LABEL   Label to put all packages into
```

move

```
usage: anaconda move [-h] [--from-label FROM_LABEL] [--to-label TO_LABEL] spec
```

Move packages between labels.

positional arguments:

```
spec                Package - written as user/package/version[/filename]
                    If filename is not given, move all files in the
                    version
```

optional arguments:

```
-h, --help            show this help message and exit
```

(continues on next page)

(continued from previous page)

```
--from-label FROM_LABEL      Label to move packages from
--to-label TO_LABEL          Label to move packages to
```

4.3.5 Glossary

- *Anaconda*

- *Anaconda Client CLI*
- *Binstar*
- *conda*
- *conda build*
- *conda package*
- *label*
- *Miniconda*
- *namespace*
- *noarch package*
- *on-site repository*
- *organization account*
- *package*
- *package manager*
- *repository*
- *source package*
- *token*

Anaconda

An easy-to-install, free collection of open source packages, including Python and the conda package manager, with free community support. Over 150 packages are installed with Anaconda. After installing Anaconda, you can install or update over 250 additional open source packages contained in the Anaconda repository using the `conda install PACKAGENAME` command.

NOTE: Replace `PACKAGENAME` with the name of the desired package.

Anaconda Cloud

[Anaconda Cloud](#) is a package management service by [Anaconda](#). Cloud makes it easy to find, access, store and share public notebooks, environments, and conda and PyPI packages. Cloud also makes it easy to stay current with updates made to the packages and environments you are using.

Cloud hosts hundreds of useful Python packages, notebooks and environments for a wide variety of applications. You do not need a Cloud account, or to be logged in, to search for public packages, download and install them.

For more information, see the [introduction to Anaconda Cloud](#).

Anaconda Client CLI

The Anaconda Client command line interface (CLI) allows you to log into Cloud directly from your terminal window and manage your account. It is not necessary for downloading or installing packages from Cloud.

Binstar

Binstar was an early project name for Cloud. You may still see the term Binstar in certain command and directory names.

conda

The conda package manager and environment manager program that installs and updates packages and their dependencies, and lets you easily switch between environments on your local computer.

conda build

The command line interface that lets you build packages for your local operating system.

conda package

A compressed file containing system-level libraries, Python modules, executable programs or other components. The file uses the tarball format.

label

Part of the URLs on Cloud where conda looks for packages. Labels are searched only if you specify a label.

The default label is `main`, so packages that are uploaded without specifying a label are automatically labeled `main`. The version labeled `main` is also downloaded by default, unless a user specifies a different label.

So, if a file is labeled `main`, then the label name may be omitted from the URL. For example, the following repositories are equivalent:

```
https://anaconda.org/sean/labels/main
https://anaconda.org/sean
```

Commands such as `conda install` can be used with a channel or used with a channel and a label:

```
conda install --channel sean selenium
conda install --channel sean/label/dev selenium
conda install --channel sean/label/stable selenium
```

Miniconda

A minimal installer for *conda*. Like *Anaconda*, Miniconda is a software package that includes the conda package manager and Python and its dependencies. However, Miniconda does not include any other packages. Once conda is installed by installing either Anaconda or Miniconda, you can install other software packages directly from the command line using `conda install`.

namespace

Each user and organization has their own location called a “namespace” where they may host packages. You can view the public packages in a user or organization’s namespace by navigating to their user page.

EXAMPLE: The `travis` user namespace located at <https://anaconda.org/travis> contains packages that were uploaded and shared by the user whose account is named `travis`.

noarch package

A conda package that contains nothing specific to any system architecture, so it may be installed on any system. When conda searches for packages on any system in a channel, conda always checks both the system-specific subdirectory, for example, `linux-64` and the `noarch` directory.

on-site repository

Cloud is powered by Anaconda Repository by Anaconda, Inc. You can run your own private repository behind firewalls or in air-gapped environments. For more information, contact sales@anaconda.com.

organization account

An organization account is a type of account on Cloud that allows multiple individual users to administer packages and control package access to different user groups. It also includes a large amount of storage space.

package

All files uploaded to Cloud are stored in packages. Each Cloud package is visible at its own unique URL based on the name of the user who owns the package and the name of the package.

For example, if a user `travis` uploads a test package named `testpkg`, it is visible at:

`https://anaconda.org/travis/testpkg`

Cloud packages may contain multiple files, and these files may be data files such as comma separated value (CSV), tab separated value (TSV), or text (TXT), or package files such as conda packages, PyPI packages or R packages.

NOTE: All packages are public if uploaded by users of free accounts. Packages may be designated as private by upgrading to a paid account.

package manager

A package manager is a tool that facilitates the process of installing, upgrading, configuring and removing packages, including the packages on Cloud. Cloud supports two package managers, *conda* and *PyPI*.

For more information, see *using package managers*.

repository

A storage location from which software packages may be retrieved and installed on a computer.

source package

“Source” packages are source code only, not yet built for any specific platform, and might be compatible with all, some or only one of the platforms.

token

A token—or authentication token—is the mechanism by which anonymous users can download private packages without using a Cloud account. It is an alpha-numeric code that is inserted into a URL that allows access by anyone who has the URL. You can use Client to generate new tokens to give other users specifically scoped access to packages and collections.

4.4 Archive

This is the archive of Anaconda products that are no longer in production. This documentation is provided as a courtesy for customers who still use them.

4.4.1 Anaconda Accelerate

High Performance Computing

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it. SEE <https://www.anaconda.com/blog/developer-blog/open-sourcing-anaconda-accelerate/>

Anaconda Accelerate is a package that provides the Anaconda® platform access to several numerical libraries that are optimized for performance on Intel CPUs and NVidia GPUs.

The current version, 2.3.1, was released on January 30, 2017.

Anyone can now use the functionality from Accelerate without purchasing a license!

On July 27, 2017, Accelerate was split into the [Intel Distribution for Python](#) and the open source [Numba](#) project’s sub-projects [pyculib](#), [pyculib_sorting](#) and [data_profiler](#). Numba and all its sub-projects are available under a BSD license.

More information is available in the post [Open Sourcing Anaconda Accelerate](#).

Features

- **Bindings to the following *CUDA* libraries:**

- *cuBLAS*
- *cuFFT*
- *cuSPARSE*
- *cuRAND*

- *CUDA Sorting* algorithms from the CUB and Modern GPU libraries
- Speed-boosted linear algebra operations in NumPy, SciPy, scikit-learn and NumExpr libraries using Intel’s Math Kernel Library (*MKL*).
- Accelerated variants of Numpy’s built-in *UFuncs*.
- Increased-speed Fast Fourier Transformations (*FFT*) in NumPy.

Installation

This section contains information related to:

Requirements

- 64-bit operating system—Windows, macOS or Linux
- **Supported Python and Numpy combinations:**
 - Python 2.7 with Numpy 1.9, 1.10 or 1.11
 - Python 3.4 with Numpy 1.9, 1.10 or 1.11
 - Python 3.5 with Numpy 1.9, 1.10 or 1.11
 - Python 3.6 with Numpy 1.11
- Numba 0.30

CUDA feature requirements

- NVidia driver version 349.00 or later
- CUDA toolkit 7.0
- At least one CUDA GPU with compute capability 2.0 or above

Installing Accelerate

Accelerate is included with Anaconda Workgroup and Anaconda Enterprise [subscriptions](#).

To start a 30-day free trial, download and install the Anaconda Accelerate package.

Installing with Anaconda

If you already have the *Anaconda free Python distribution* <<http://anaconda.com/downloads.html>>, take the following steps to install Accelerate:

1. Run the command `conda update conda`.
2. Run the command `conda install accelerate`.

If you do not have Anaconda installed, see [Downloads](#).

NOTE: Accelerate can also be installed into your own non-Anaconda Python environment.

For more information, contact sales@anaconda.com.

Updating Accelerate

To update Accelerate, take the following steps:

1. Run the command `conda update conda`.
2. Run the command `conda update accelerate`.

Updating NumbaPro

If you have NumbaPro installed, you must manually upgrade NumbaPro to install the NumbaPro compatibility layer by taking the following steps:

1. Run the command `conda update conda`.
2. Run the command `conda update numbapro`.

Managing your Accelerate license

You can install, view or remove your Accelerate license with the graphical Anaconda Navigator license manager, or manually with your operating system.

For more information, see </anaconda/user-guide/tasks/install-licenses>.

User guide

This section contains information related to:

CUDA libraries

The following CUDA libraries have bindings and algorithms that are available for use with Accelerate:

cuBLAS

Provides basic linear algebra building blocks. See [NVIDIA cuBLAS](#).

The cuBLAS binding provides an interface that accepts NumPy arrays and Numba's CUDA device arrays. The binding automatically transfers NumPy array arguments to the device as required. This automatic transfer may generate some unnecessary transfers, so optimal performance is likely to be obtained by the manual transfer for NumPy arrays into device arrays and using the cuBLAS to manipulate device arrays where possible.

No special naming convention is used to identify the data type, unlike in the BLAS C and Fortran APIs. Arguments for array storage information which are part of the cuBLAS C API are also not necessary since NumPy arrays and device arrays contain this information.

All functions are accessed through the `accelerate.cuda.blas.Blas` class:

BLAS Level 1

`accelerate.cuda.blas.Blas.nrm2(x)`

Computes the L2 norm for array *x*. Same as *numpy.linalg.norm(x)*.

Parameters **x** (*python.array*) – input vector

Returns resulting norm.

`accelerate.cuda.blas.Blas.dot(x, y)`

Compute the dot product of array *x* and array *y*. Same as *np.dot(x, y)*.

Parameters

- **x** (*python.array*) – vector
- **y** (*python.array*) – vector

Returns dot product of *x* and *y*

`accelerate.cuda.blas.Blas.dotc(x, y)`

Uses the conjugate of the element of the vectors to compute the dot product of array *x* and array *y* for complex dtype only. Same as *np.vdot(x, y)*.

Parameters

- **x** (*python.array*) – vector
- **y** (*python.array*) – vector

Returns dot product of *x* and *y*

`accelerate.cuda.blas.Blas.scal(alpha, x)`

Scale *x* inplace by *alpha*. Same as *x = alpha * x*

Parameters

- **alpha** – scalar
- **x** (*python.array*) – vector

`accelerate.cuda.blas.Blas.axpy(alpha, x)`

Compute *y = alpha * x + y* inplace.

Parameters

- **alpha** – scalar
- **x** (*python.array*) – vector

`accelerate.cuda.blas.Blas.amax(x)`

Find the index of the first largest element in array *x*. Same as *np.argmax(x)*

Parameters **x** (*python.array*) – vector

Returns index (start from 0).

`accelerate.cuda.blas.Blas.amin(x)`

Find the index of the first largest element in array *x*. Same as *np.argmin(x)*

Parameters **x** (*python.array*) – vector

Returns index (start from 0).

`accelerate.cuda.blas.Blas.asum(x)`

Compute the sum of all element in array *x*.

Parameters **x** (*python.array*) – vector

Returns *x.sum()*

`accelerate.cuda.blas.Blas.rot(x, y, c, s)`

Apply the Givens rotation matrix specified by the cosine element c and the sine element s inplace on vector element x and y .

Same as $x, y = c * x + s * y, -s * x + c * y$

Parameters

- **x** (`python.array`) – vector
- **y** (`python.array`) – vector

`accelerate.cuda.blas.Blas.rotg(a, b)`

Constructs the Givens rotation matrix with the column vector (a, b).

Parameters

- **a** – first element of the column vector
- **b** – second element of the column vector

Returns

a tuple (r, z, c, s)

$r - r = a^{**2} + b^{**2}$

z – Use to reconstruct c and s . Refer to cuBLAS documentation for detail.

c – The consine element.

s – The sine element.

`accelerate.cuda.blas.Blas.rotm(x, y, param)`

Applies the modified Givens transformation inplace.

Same as:

```
param = flag, h11, h21, h12, h22
x[i] = h11 * x[i] + h12 * y[i]
y[i] = h21 * x[i] + h22 * y[i]
```

Refer to the cuBLAS documentation for the use of *flag*.

Parameters

- **x** (`python.array`) – vector
- **y** (`python.array`) – vector

`accelerate.cuda.blas.Blas.rotmg(d1, d2, x1, y1)`

Constructs the modified Givens transformation H that zeros out the second entry of a column vector ($d1 * x1, d2 * y1$).

Parameters

- **d1** – scaling factor for the x-coordinate of the input vector
- **d2** – scaling factor for the y-coordinate of the input vector
- **x1** – x-coordinate of the input vector
- **y1** – y-coordinate of the input vector

Returns A 1D array that is usable in *rotm*. The first element is the flag for *rotm*. The rest of the elements corresponds to the *h11, h21, h12, h22* elements of H .

BLAS Level 2

All level 2 routines follow the following naming convention for all arguments:

- **A, B, C, AP – (2D array) Matrix argument.** *AP* implies packed storage for banded matrix.
- *x, y, z* – (1D arrays) Vector argument.
- *alpha, beta* – (scalar) Can be floats or complex numbers depending.
- *m* – (scalar) Number of rows of matrix *A*.
- ***n* – (scalar) Number of columns of matrix *A*. If *m* is not needed, *n* also means the number of rows of the matrix *A*; thus, implying a square matrix.**
- ***trans, transa, transb* – (string)** Select the operation *op* to apply to a matrix:
 - ‘N’: $op(X) = X$, the identity operation;
 - ‘T’: $op(X) = X^{**T}$, the transpose;
 - ‘C’: $op(X) = X^{**H}$, the conjugate transpose.

trans only applies to the only matrix argument. *transa* and *transb* apply to matrix *A* and matrix *B*, respectively.
- ***uplo* – (string) Can be ‘U’ for filling the upper triangular matrix; or ‘L’ for filling the lower triangular matrix.**
- *diag* – (boolean) Whether the matrix diagonal has unit elements.
- ***mode* – (string) ‘L’ means the matrix is on the left side in the equation.** ‘R’ means the matrix is on the right side in the equation.

Note: The last array argument is always overwritten with the result.

`accelerate.cuda.blas.Blas.gbmv(trans, m, n, kl, ku, alpha, A, x, beta, y)`
banded matrix-vector multiplication $y = \alpha * op(A) * x + \beta * y$ where *A* has *kl* sub-diagonals and *ku* super-diagonals.

`accelerate.cuda.blas.Blas.gemv(trans, m, n, alpha, A, x, beta, y)`
matrix-vector multiplication $y = \alpha * op(A) * x + \beta * y$

`accelerate.cuda.blas.Blas.trmv(uplo, trans, diag, n, A, x)`
triangular matrix-vector multiplication $x = op(A) * x$

`accelerate.cuda.blas.Blas.tbmvm(uplo, trans, diag, n, k, A, x)`
triangular banded matrix-vector $x = op(A) * x$

`accelerate.cuda.blas.Blas.tpmvm(uplo, trans, diag, n, AP, x)`
triangular packed matrix-vector multiplication $x = op(A) * x$

`accelerate.cuda.blas.Blas.trsv(uplo, trans, diag, n, A, x)`
Solves the triangular linear system with a single right-hand-side. $op(A) * x = b$

`accelerate.cuda.blas.Blas.tpsvm(uplo, trans, diag, n, AP, x)`
Solves the packed triangular linear system with a single right-hand-side. $op(A) * x = b$

`accelerate.cuda.blas.Blas.tbsvm(uplo, trans, diag, n, k, A, x)`
Solves the triangular banded linear system with a single right-hand-side. $op(A) * x = b$

`accelerate.cuda.blas.Blas.symvm(uplo, n, alpha, A, x, beta, y)`
symmetric matrix-vector multiplication $y = \alpha * A * x + \beta * y$

```

accelerate.cuda.blas.Blas.hemv(uplo, n, alpha, A, x, beta, y)
    Hermitian matrix-vector multiplication  $y = \alpha * A * x + \beta * y$ 

accelerate.cuda.blas.Blas.sbmv(uplo, n, k, alpha, A, x, beta, y)
    symmetric banded matrix-vector multiplication  $y = \alpha * A * x + \beta * y$ 

accelerate.cuda.blas.Blas.hbmV(uplo, n, k, alpha, A, x, beta, y)
    Hermitian banded matrix-vector multiplication  $y = \alpha * A * x + \beta * y$ 

accelerate.cuda.blas.Blas.spmv(uplo, n, alpha, AP, x, beta, y)
    symmetric packed matrix-vector multiplication  $y = \alpha * A * x + \beta * y$ 

accelerate.cuda.blas.Blas.hpmv(uplo, n, alpha, AP, x, beta, y)
    Hermitian packed matrix-vector multiplication  $y = \alpha * A * x + \beta * y$ 

accelerate.cuda.blas.Blas.ger(m, n, alpha, x, y, A)
    the rank-1 update  $A := \alpha * x * y ** T + A$ 

accelerate.cuda.blas.Blas.geru(m, n, alpha, x, y, A)
    the rank-1 update  $A := \alpha * x * y ** T + A$ 

accelerate.cuda.blas.Blas.gerc(m, n, alpha, x, y, A)
    the rank-1 update  $A := \alpha * x * y ** H + A$ 

accelerate.cuda.blas.Blas.syr(uplo, n, alpha, x, A)
    symmetric rank 1 operation  $A := \alpha * x * x ** T + A$ 

accelerate.cuda.blas.Blas.her(uplo, n, alpha, x, A)
    hermitian rank 1 operation  $A := \alpha * x * x ** H + A$ 

accelerate.cuda.blas.Blas.spr(uplo, n, alpha, x, AP)
    the symmetric rank 1 operation  $A := \alpha * x * x ** T + A$ 

accelerate.cuda.blas.Blas.hpr(uplo, n, alpha, x, AP)
    hermitian rank 1 operation  $A := \alpha * x * x ** H + A$ 

accelerate.cuda.blas.Blas.syr2(uplo, n, alpha, x, y, A)
    symmetric rank-2 update  $A = \alpha * x * y ** T + y * x ** T + A$ 

accelerate.cuda.blas.Blas.her2(uplo, n, alpha, x, y, A)
    Hermitian rank-2 update  $A = \alpha * x * y ** H + \alpha * y * x ** H + A$ 

accelerate.cuda.blas.Blas.spr2(uplo, n, alpha, x, y, A)
    packed symmetric rank-2 update  $A = \alpha * x * y ** T + y * x ** T + A$ 

accelerate.cuda.blas.Blas.hpr2(uplo, n, alpha, x, y, A)
    packed Hermitian rank-2 update  $A = \alpha * x * y ** H + \alpha * y * x ** H + A$ 

```

BLAS Level 3

All level 3 routines follow the same naming convention for arguments as in level 2 routines.

```

accelerate.cuda.blas.Blas.gemm(transa, transb, m, n, k, alpha, A, B, beta, C)
    matrix-matrix multiplication  $C = \alpha * op(A) * op(B) + \beta * C$ 

accelerate.cuda.blas.Blas.syrk(uplo, trans, n, k, alpha, A, beta, C)
    symmetric rank- k update  $C = \alpha * op(A) * op(A) ** T + \beta * C$ 

accelerate.cuda.blas.Blas.herk(uplo, trans, n, k, alpha, A, beta, C)
    Hermitian rank- k update  $C = \alpha * op(A) * op(A) ** H + \beta * C$ 

```

`accelerate.cuda.blas.Blas.symm(side, uplo, m, n, alpha, A, B, beta, C)`
symmetric matrix-matrix multiplication:

```
if side == 'L':
    C = alpha * A * B + beta * C
else: # side == 'R'
    C = alpha * B * A + beta * C
```

`accelerate.cuda.blas.Blas.hemm(side, uplo, m, n, alpha, A, B, beta, C)`
Hermitian matrix-matrix multiplication:

```
if side == 'L':
    C = alpha * A * B + beta * C
else: # side == 'R':
    C = alpha * B * A + beta * C
```

`accelerate.cuda.blas.Blas.trsm(side, uplo, trans, diag, m, n, alpha, A, B)`
Solves the triangular linear system with multiple right-hand-sides:

```
if side == 'L':
    op(A) * X = alpha * B
else: # side == 'R'
    X * op(A) = alpha * B
```

`accelerate.cuda.blas.Blas.trmm(side, uplo, trans, diag, m, n, alpha, A, B, C)`
triangular matrix-matrix multiplication:

```
if side == ':':
    C = alpha * op(A) * B
else: # side == 'R'
    C = alpha * B * op(A)
```

`accelerate.cuda.blas.Blas.dgmm(side, m, n, A, x, C)`
matrix-matrix multiplication:

```
if mode == 'R':
    C = A * x * diag(X)
else: # mode == 'L'
    C = diag(X) * x * A
```

`accelerate.cuda.blas.Blas.geam(transa, transb, m, n, alpha, A, beta, B, C)`
matrix-matrix addition/transposition $C = \alpha * op(A) + \beta * op(B)$

cuSPARSE

Provides basic linear algebra operations for sparse matrices. See [NVIDIA cuSPARSE](#) for an in-depth description of the cuSPARSE library and its methods and data types. All functions are accessed through the `accelerate.cuda.sparse.Sparse` class:

Similarly to the cuBLAS interface, no special naming convention is used for functions to operate on different datatypes - all datatypes are handled by each function, and dispatch of the corresponding library function is handled by Accelerate. However, it is often necessary to provide a *matrix descriptor* to functions, which provides some information about the format and properties of a matrix. A matrix descriptor can be obtained from the `accelerate.cuda.sparse.Sparse.matdescr()` method:

`accelerate.cuda.sparse.Sparse.matdescr (indexbase, diagtype, fillmode, matrixtype)`

Creates a matrix descriptor that describes a matrix with the given *indexbase*, *diagtype*, *fillmode*, and *matrixtype*. Note that not all of these options are relevant to every matrix storage format.

Parameters

- **indexbase** – Optional. 0 for 0-based indexing, or 1 for 1-based indexing. If not specified, the default given to the `accelerate.cuda.sparse.Sparse` constructor is used instead.
- **diagtype** – Optional. Defaults to 'N'. 'N' signifies that the matrix diagonal has non-unit elements. 'U' signifies that the matrix diagonal only contains unit elements.
- **fillmode** – Optional. Defaults to 'L'. 'L' indicates that the lower triangular part of the matrix is stored. 'U' indicates that the upper triangular part of the matrix is stored.
- **matrixtype** – Optional. Defaults to 'G'. 'S' indicates that the matrix is symmetric. 'H' indicates that the matrix is Hermitian. 'T' indicates that the matrix is triangular. 'G' is used for a *general* matrix, which is not symmetric, Hermitian, or triangular.

Returns A matrix descriptor.

Many of the methods of the `accelerate.cuda.sparse.Sparse` class accept the individual data structures that make up a sparse representation of a matrix (for example the values, the row pointers and the column indices for a CSR format matrix). However, some methods (such as `accelerate.cuda.sparse.Sparse.csr_gemm_ez()`), accept an instance of the `accelerate.cuda.sparse.CudaSparseMatrix` class:

class `accelerate.cuda.sparse.CudaSparseMatrix`

Base class for a representation of a sparse matrix on a CUDA device. The constructor takes no arguments.

from_host_matrix (*matrix*, *stream*)

Initialise the matrix structure and values from an instance of a matrix on the host. The host matrix must be of the corresponding host type, which is documented for each subclass below.

copy_to_host (*stream*)

Create an instance of the corresponding host matrix type and copy the matrix structure and data into it from the device. See subclass documentation for an indication of the corresponding matrix type.

Subclasses of the sparse matrix type are:

class `accelerate.cuda.sparse.CudaBSRMatrix`

CUDA sparse matrix for which the corresponding type is a `scipy.sparse.bsr_matrix`.

class `accelerate.cuda.sparse.CudaCSRMatrix`

CUDA sparse matrix for which the corresponding type is a `scipy.sparse.csr_matrix`.

class `accelerate.cuda.sparse.CudaCSCMatrix`

CUDA sparse matrix for which the corresponding type is a `scipy.sparse.csc_matrix`.

There are also some convenience methods for constructing CUDA sparse matrices in a similar manner to Scipy sparse matrices:

BLAS Level 1

`accelerate.cuda.sparse.Sparse.axpyi (alpha, xVal, xInd, y)`

Multiplies the sparse vector *x* by *alpha* and adds the result to the dense vector *y*.

Parameters

- **alpha** – scalar
- **xVal** – vector of non-zero values of *x*

- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns dense vector

`accelerate.cuda.sparse.Sparse.doti(xVal, xInd, y)`

Computes the dot product of the sparse vector x and dense vector y .

Parameters

- **xVal** – vector of non-zero values of x
- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns scalar

`accelerate.cuda.sparse.Sparse.dotci(xVal, xInd, y)`

Computes the dot product of the complex conjugate of the sparse vector x and the dense vector y .

Parameters

- **xVal** – vector of non-zero values of x
- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns scalar

`accelerate.cuda.sparse.Sparse.gthr(y, xVal, xInd)`

Gathers the elements of y at the indices $xInd$ into the array $xVal$

Parameters

- **xVal** – vector of non-zero values of x
- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.gthrz(y, xVal, xInd)`

Gathers the elements of y at the indices $xInd$ into the array $xVal$ and zeroes out the gathered elements of y .

Parameters

- **xVal** – vector of non-zero values of x
- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.sctr(xVal, xInd, y)`

Scatters the elements of the sparse vector x into the dense vector y . Elements of y whose indices are not listed in $xInd$ are unmodified.

Parameters

- **xVal** – vector of non-zero values of x
- **xInd** – vector of indices of non-zero values of x
- **y** – dense vector

Returns None

BLAS Level 2

All level 2 routines follow the following naming convention for the following arguments:

- **alpha, beta** – (scalar) Can be real or complex numbers.
- **descr, descrA, descrB** – (descriptor) Matrix descriptor. An appropriate descriptor may be obtained by calling `accelerate.cuda.sparse.Sparse.matdescr()`. *descr* only applies to the only matrix argument. *descrA* and *descrB* apply to matrix *A* and matrix *B*, respectively.
- **dir** – (string) Can be 'C' to indicate column-major block storage or 'R' to indicate row-major block storage.
- **trans, transa, transb** – (string) Select the operation *op* to apply to a matrix:
 - 'N': $op(X) = X$, the identity operation;
 - 'T': $op(X) = X^{**T}$, the transpose;
 - 'C': $op(X) = X^{**H}$, the conjugate transpose.

trans only applies to the only matrix argument. *transa* and *transb* apply to matrix *A* and matrix *B*, respectively.

`accelerate.cuda.sparse.Sparse.bsrnv_matrix(dir, trans, alpha, descr, bsrmat, x, beta, y)`
 Matrix-vector multiplication $y = \alpha * op(A) * x + \beta * y$ with a BSR-format matrix.

Parameters

- **dir** – block storage direction
- **trans** – operation to apply to the matrix
- **alpha** – scalar
- **descr** – matrix descriptor
- **bsrmat** – the matrix *A*
- **x** – dense vector
- **beta** – scalar
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.bsrnv(dir, trans, mb, nb, nnzb, alpha, descr, bsrVal, bsrRowPtr, bsrColInd, blockDim, x, beta, y)`

Matrix-vector multiplication $y = \alpha * op(A) * x + \beta * y$ with a BSR-format matrix. This function accepts the individual arrays that make up the structure of a BSR matrix - if a `accelerate.cuda.sparse.CudaBSRMatrix` instance is to hand, it is recommended to use the `bsrnv_matrix()` method instead.

Parameters

- **dir** – block storage direction
- **trans** – operation to apply to the matrix
- **mb** – Number of block rows of the matrix
- **nb** – Number of block columns of the matrix
- **nnzb** – Number of nonzero blocks of the matrix
- **alpha** – scalar

- **descr** – matrix descriptor
- **bsrVal** – vector of nonzero values of the matrix
- **bsrRowPtr** – vector of block row pointers of the matrix
- **bsrColInd** – vector of block column indices of the matrix
- **blockDim** – block dimension of the matrix
- **x** – dense vector
- **beta** – scalar
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.bsrxmvm(dir, trans, sizeOfMask, mb, nb, nnzb, alpha, descr, bsrVal, bsrMaskPtr, bsrRowPtr, bsrEndPtr, bsrColInd, blockDim, x, beta, y)`

Matrix-vector multiplication similar to `bsrmv()`, but including a mask operation: $y(mask) = (\alpha * op(A) * x + \beta * y)(mask)$. The blocks of y to be updated are specified in `bsrMaskPtr`. Blocks whose indices are not specified in `bsrMaskPtr` are left unmodified.

Parameters

- **dir** – block storage direction
- **trans** – operation to apply to the matrix
- **sizeOfMask** – number of updated blocks of rows of y
- **mb** – Number of block rows of the matrix
- **nb** – Number of block columns of the matrix
- **nnzb** – Number of nonzero blocks of the matrix
- **alpha** – scalar
- **descr** – matrix descriptor
- **bsrVal** – vector of nonzero values of the matrix
- **bsrMaskPtr** – vector of indices of the block elements to be updated
- **bsrRowPtr** – vector of block row pointers of the matrix
- **bsrEndPtr** – vector of pointers to the end of every block row plus one
- **bsrColInd** – vector of block column indices of the matrix
- **blockDim** – block dimension of the matrix
- **x** – dense vector
- **beta** – scalar
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.csrmv(trans, m, n, nnz, alpha, descr, csrVal, csrRowPtr, csrColInd, x, beta, y)`

Matrix-vector multiplication $y = \alpha * op(A) * x + \beta * y$ with a CSR-format matrix.

Parameters

- **trans** – operation to apply to the matrix

- **m** – Number of rows of the matrix
- **n** – Number of columns of the matrix
- **nnz** – Number of nonzeros of the matrix
- **alpha** – scalar
- **descr** – matrix descriptor
- **csrVal** – vector of nonzero values of the matrix
- **csrRowPtr** – vector of row pointers of the matrix
- **csrColInd** – vector of column indices of the matrix
- **x** – dense vector
- **beta** – scalar
- **y** – dense vector

Returns None

`accelerate.cuda.sparse.Sparse.csrsv_analysis(trans, m, nnz, descr, csrVal, csrRowPtr, csrColInd)`

Performs the analysis phase of the solution of the sparse triangular linear system $op(A) * y = alpha * x$. This needs to be executed only once for a given matrix and operation type.

Parameters

- **trans** – operation to apply to the matrix
- **m** – number of rows of the matrix
- **nnz** – number of nonzeros of the matrix
- **descr** – matrix descriptor
- **csrVal** – vector of nonzero values of the matrix
- **csrRowPtr** – vector of row pointers of the matrix
- **csrColInd** – vector of column indices of the matrix

Returns the analysis result, which can be used as input to the solve phase

`accelerate.cuda.sparse.Sparse.csrsv_solve(trans, m, alpha, descr, csrVal, csrRowPtr, csrColInd, info, x, y)`

Performs the analysis phase of the solution of the sparse triangular linear system $op(A) * y = alpha * x$.

Parameters

- **trans** – operation to apply to the matrix
- **m** – number of rows of the matrix
- **alpha** – scalar
- **descr** – matrix descriptor
- **csrVal** – vector of nonzero values of the matrix
- **csrRowPtr** – vector of row pointers of the matrix
- **csrColInd** – vector of column indices of the matrix
- **info** – the analysis result from `csrsv_analysis()`
- **x** – dense vector

- **y** – dense vector into which the solve result is stored

Returns None

BLAS Level 3

`accelerate.cuda.sparse.Sparse.csrmm` (*transA, m, n, k, nnz, alpha, descrA, csrValA, csrRowPtrA, csrColIndA, B, ldb, beta, C, ldc*)

Matrix-matrix multiplication $C = \alpha * op(A) * B + \beta * C$ where A is a sparse matrix in CSR format and B and C are dense matrices.

Parameters

- **transA** – operation to apply to A
- **m** – number of rows of A
- **n** – number of columns of B and C
- **k** – number of columns of A
- **nnz** – number of nonzeros in A
- **alpha** – scalar
- **descrA** – matrix descriptor
- **csrValA** – vector of nonzero values of A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **B** – dense matrix
- **ldb** – leading dimension of B
- **beta** – scalar
- **C** – dense matrix
- **ldc** – leading dimension of C

Returns None

`accelerate.cuda.sparse.Sparse.csrmm2` (*transA, transB, m, n, k, nnz, alpha, descrA, csrValA, csrRowPtrA, csrColIndA, B, ldb, beta, C, ldc*)

Matrix-matrix multiplication $C = \alpha * op(A) * op(B) + \beta * C$ where A is a sparse matrix in CSR format and B and C are dense matrices.

Parameters

- **transA** – operation to apply to A
- **transB** – operation to apply to B
- **m** – number of rows of A
- **n** – number of columns of B and C
- **k** – number of columns of A
- **nnz** – number of nonzeros in A
- **alpha** – scalar
- **descrA** – matrix descriptor

- **csrValA** – vector of nonzero values of A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **B** – dense matrix
- **ldb** – leading dimension of B
- **beta** – scalar
- **C** – dense matrix
- **ldc** – leading dimension of C

Returns None

`accelerate.cuda.sparse.Sparse.csrsm_analysis(transA, m, nnz, descrA, csrValA, csrRowPtrA, csrColIndA)`

Performs the analysis phase of the solution of a sparse triangular linear system $op(A) * Y = alpha * X$ with multiple right-hand sides where A is a sparse matrix in CSR format, and X and Y are dense matrices.

Parameters

- **transA** – operation to apply to A
- **m** – number of rows of A
- **nnz** – number of nonzeros in A
- **descrA** – matrix descriptor
- **csrValA** – vector of nonzero values of A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A

Returns the analysis result

`accelerate.cuda.sparse.Sparse.csrsm_solve(transA, m, n, alpha, descrA, csrValA, csrRowPtrA, csrColIndA, info, X, ldx, Y, ldy)`

Performs the analysis phase of the solution of a sparse triangular linear system $op(A) * Y = alpha * X$ with multiple right-hand sides where A is a sparse matrix in CSR format, and X and Y are dense matrices.

Parameters

- **transA** – operation to apply to A
- **m** – number of rows of A
- **n** – number of columns of B and C
- **alpha** – scalar
- **descrA** – matrix descriptor
- **csrValA** – vector of nonzero values of A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **info** – the analysis result from `csrsm_analysis()`
- **X** – dense matrix
- **ldx** – leading dimension of X

- **Y** – dense matrix
- **ldy** – leading dimension of *Y*

Returns None

Extra Functions

`accelerate.cuda.sparse.Sparse.XcsrgeamNnz` (*m*, *n*, *descrA*, *nnzA*, *csrRowPtrA*, *csrColIndA*,
descrB, *nnzB*, *csrRowPtrB*, *csrColIndB*, *descrC*,
csrRowPtrC)

Set up the sparsity pattern for the matrix operation $C = \alpha * A + \beta * B$ where *A*, *B*, and *C* are all sparse matrices in CSR format.

Parameters

- **m** – number of rows of all matrices
- **n** – number of columns of all matrices
- **descrA** – matrix descriptor for *A*
- **nnzA** – number of nonzeros in *A*
- **csrRowPtrA** – vector of row pointers of *A*
- **csrColIndA** – vector of column indices of *A*
- **descrB** – matrix descriptor for *B*
- **nnzB** – number of nonzeros in *B*
- **csrRowPtrB** – vector of row pointers of *B*
- **csrColIndB** – vector of column indices of *B*
- **descrC** – matrix descriptor for *B*
- **csrRowPtrC** – vector of row pointers of *C*, written to by this method

Returns number of nonzeros in *C*

`accelerate.cuda.sparse.Sparse.csrgeam` (*m*, *n*, *alpha*, *descrA*, *nnzA*, *csrValA*, *csrRowPtrA*, *csrColIndA*, *beta*, *descrB*, *nnzB*, *csrValB*, *csrRowPtrB*, *csrColIndB*, *descrC*, *csrValC*, *csrRowPtrC*, *csrColIndC*)

Performs the the matrix operation $C = \alpha * A + \beta * B$ where *A*, *B*, and *C* are all sparse matrices in CSR format.

Parameters

- **m** – number of rows of all matrices
- **n** – number of columns of all matrices
- **alpha** – scalar
- **descrA** – matrix descriptor for *A*
- **nnzA** – number of nonzeros in *A*
- **csrValA** – vector of nonzero values of *A*
- **csrRowPtrA** – vector of row pointers of *A*
- **csrColIndA** – vector of column indices of *A*

- **beta** – scalar
- **descrB** – matrix descriptor for B
- **nnzB** – number of nonzeros in B
- **csrValB** – vector of nonzero values of B
- **csrRowPtrB** – vector of row pointers of B
- **csrColIndB** – vector of column indices of B
- **descrC** – matrix descriptor for C
- **csrValC** – vector of nonzero values of C
- **csrRowPtrC** – vector of row pointers of C
- **csrColIndC** – vector of column indices of C

Returns None

`accelerate.cuda.sparse.Sparse.XcsrgermmNnz` (*transA, transB, m, n, k, descrA, nnzA, csrRowPtrA, csrColIndA, descrB, nnzB, csrRowPtrB, csrColIndB, descrC, csrRowPtrC*)

Set up the sparsity pattern for the matrix operation $C = op(A) * op(B)$ where A , B , and C are all sparse matrices in CSR format.

Parameters

- **transA** – operation to apply to A
- **transB** – operation to apply to B
- **m** – number of rows of A and C
- **n** – number of columns of B and C
- **k** – number of columns/rows of A/B
- **descrA** – matrix descriptor for A
- **nnzA** – number of nonzeros in A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **descrB** – matrix descriptor for B
- **nnzB** – number of nonzeros in B
- **csrRowPtrB** – vector of row pointers of B
- **csrColIndB** – vector of column indices of B
- **descrC** – matrix descriptor for C
- **csrRowPtrC** – vector of row pointers of C , written by this function

Returns number of nonzeros in C

`accelerate.cuda.sparse.Sparse.csrgermm` (*transA, transB, m, n, k, descrA, nnzA, csrValA, csrRowPtrA, csrColIndA, descrB, nnzB, csrValB, csrRowPtrB, csrColIndB, descrC, csrValC, csrRowPtrC, csrColIndC*)

Perform the matrix operation $C = op(A) * op(B)$ where A , B , and C are all sparse matrices in CSR format.

Parameters

- **transA** – operation to apply to *A*
- **transB** – operation to apply to *B*
- **m** – number of rows of *A* and *C*
- **n** – number of columns of *B* and *C*
- **k** – number of columns/rows of *A/B*
- **descrA** – matrix descriptor for *A*
- **nnzA** – number of nonzeros in *A*
- **csrValA** – vector of nonzero values in *A*
- **csrRowPtrA** – vector of row pointers of *A*
- **csrColIndA** – vector of column indices of *A*
- **descrB** – matrix descriptor for *B*
- **nnzB** – number of nonzeros in *B*
- **csrValB** – vector of nonzero values in *B*
- **csrRowPtrB** – vector of row pointers of *B*
- **csrColIndB** – vector of column indices of *B*
- **descrC** – matrix descriptor for *C*
- **csrValC** – vector of nonzero values in *C*
- **csrRowPtrC** – vector of row pointers of *C*
- **csrColIndC** – vector of column indices of *C*

Returns None

```
accelerate.cuda.sparse.Sparse.csrgermm_ez(A, B, transA='N', transB='N', descrA=None, descrB=None, descrC=None)
```

Performs the matrix operation $C = op(A) * op(B)$ where *A*, *B* and *C* are all sparse matrices in CSR format. This function accepts and returns `accelerate.cuda.sparse.CudaCSRMatrix` matrices, and makes calls to `XcsrgermmNnz()` and `csrgermm()`.

Parameters

- **A** – `accelerate.cuda.sparse.CudaCSRMatrix`
- **B** – `accelerate.cuda.sparse.CudaCSRMatrix`
- **transA** – optional, operation to apply to *A*
- **transB** – optional, operation to apply to *B*
- **descrA** – optional, matrix descriptor for *A*
- **descrB** – optional, matrix descriptor for *B*
- **descrC** – optional, matrix descriptor for *C*

Returns `accelerate.cuda.sparse.CudaCSRMatrix`

Preconditioners

`accelerate.cuda.sparse.Sparse.csric0(trans, m, descr, csrValA, csrRowPtrA, csrColIndA, info)`

Computes incomplete Cholesky factorization of a sparse matrix in CSR format with 0 fill-in and no pivoting: $op(A) = R^{**T} * R$. This method must follow a call to `csrsv_analysis()`. The matrix A is overwritten with the upper or lower triangular factors R or R^{**T} .

Parameters

- **trans** – operation to apply to the matrix
- **m** – number of rows and columns of the matrix
- **descr** – matrix descriptor
- **csrValA** – vector of nonzero values in A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **info** – analysis result

Returns None

`accelerate.cuda.sparse.Sparse.csrilu0(trans, m, descr, csrValA, csrRowPtrA, csrColIndA, info)`

Computes incomplete-LU factorization of a sparse matrix in CSR format with 0 fill-in and no pivoting: $op(A) = L * U$. This method must follow a call to `csrsv_analysis()`. The matrix A is overwritten with the lower and upper triangular factors L and U .

Parameters

- **trans** – operation to apply to the matrix
- **m** – number of rows and columns of the matrix
- **descr** – matrix descriptor
- **csrValA** – vector of nonzero values in A
- **csrRowPtrA** – vector of row pointers of A
- **csrColIndA** – vector of column indices of A
- **info** – analysis result

Returns None

`accelerate.cuda.sparse.Sparse.gtsv(m, n, dl, d, du, B, ldb)`

Computes the solution of a tridiagonal linear system with multiple right-hand sides: $A * Y = alpha * X$.

Parameters

- **m** – the size of the linear system
- **n** – the number of right-hand sides in the system
- **dl** – dense vector storing the lower-diagonal elements
- **d** – dense vector storing the diagonal elements
- **du** – dense vector storing the upper-diagonal elements
- **B** – dense matrix holding the right-hand sides of the system
- **ldb** – the leading dimension of B

Returns None

`accelerate.cuda.sparse.Sparse.gtsv_nopivot(m, n, dl, d, du, B, ldb)`
Similar to `gtsv()`, but computes the solution without performing any pivoting.

Parameters

- **m** – the size of the linear system
- **n** – the number of right-hand sides in the system
- **dl** – dense vector storing the lower-diagonal elements
- **d** – dense vector storing the diagonal elements
- **du** – dense vector storing the upper-diagonal elements
- **B** – dense matrix holding the right-hand sides of the system
- **ldb** – the leading dimension of *B*

Returns None

`accelerate.cuda.sparse.Sparse.gtsvStridedBatch(m, dl, d, du, x, batchCount, batchStride)`
Computes the solution of *i* tridiagonal linear systems: $A(i) * y(i) = alpha * x(i)$.

Parameters

- **m** – the size of the linear systems
- **dl** – stacked dense vector storing the lower-diagonal elements of each system
- **d** – stacked dense vector storing the diagonal elements of each system
- **du** – stacked dense vector storing the upper-diagonal elements of each system
- **x** – dense matrix holding the right-hand sides of the systems
- **batchCount** – number of systems to solve
- **batchStride** – number of elements separating the vectors of each system

Returns None

Format Conversion

`accelerate.cuda.sparse.Sparse.bsr2csr(dirA, mb, nb, descrA, bsrValA, bsrRowPtrA, bsrColIndA, blockDim, descrC, csrValC, csrRowPtrC, csrColIndC)`

Convert the sparse matrix *A* in BSR format to CSR format, stored in *C*.

Parameters

- **dirA** – row ('R') or column ('C') orientation of block storage
- **mb** – number of block rows of *A*
- **nb** – number of block columns of *A*
- **descrA** – matrix descriptor for *A*
- **bsrValA** – vector of nonzero values of *A*
- **bsrRowPtrA** – vector of block row pointers of *A*
- **bsrColIndA** – vector of block column indices of *A*
- **blockDim** – block dimension of *A*

- **descrC** – matrix descriptor for *C*
- **csrValA** – vector of nonzero values in *C*
- **csrRowPtrA** – vector of row pointers of *C*
- **csrColIndA** – vector of column indices of *C*

Returns None

`accelerate.cuda.sparse.Sparse.Xcoo2csr (cooRowInd, nnz, m, csrRowPtr)`

Converts an array containing uncompressed row indices corresponding to the COO format into an array of compressed row pointers corresponding to the CSR format.

Parameters

- **cooRowInd** – integer array of uncompressed row indices
- **nnz** – number of nonzeros
- **m** – number of matrix rows
- **csrRowPtr** – vector of row pointers to be written to

Returns None

`accelerate.cuda.sparse.Sparse.csc2dense (m, n, descrA, cscValA, cscRowIndA, cscColPtrA, A, lda)`

Convert the sparse matrix *A* in CSC format into a dense matrix.

Parameters

- **m** – number of rows of *A*
- **n** – number of columns of *A*
- **descrA** – matrix descriptor for *A*
- **cscValA** – values in the CSC representation of *A*
- **cscRowIndA** – row indices in the CSC representation of *A*
- **cscColPtrA** – column pointers in the CSC representation of *A*
- **A** – dense matrix representation of *A* to be written by this function.
- **lda** – leading dimension of *A*

Returns None

`accelerate.cuda.sparse.Sparse.Xcsr2bsrNnz (dirA, m, n, descrA, csrRowPtrA, csrColIndA, blockDim, descrC, bsrRowPtrC)`

Performs the analysis necessary for converting a matrix in CSR format into BSR format.

Parameters

- **dirA** – row ('R') or column ('C') orientation of block storage
- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **descrA** – matrix descriptor for input matrix *A*
- **csrRowPtrA** – row pointers of matrix
- **csrColIndA** – column indices of matrix
- **blockDim** – block dimension of output matrix *C*

- **descrC** – matrix descriptor for output matrix *C*

Returns number of nonzeros of matrix

`accelerate.cuda.sparse.Sparse.csr2bsr` (*dirA, m, n, descrA, csrValA, csrRowPtrA, csrColIndA, blockDim, descrC, bsrValC, bsrRowPtrC, bsrColIndC*)

Performs conversion of a matrix from CSR format into BSR format.

Parameters

- **dirA** – row ('R') or column ('C') orientation of block storage
- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **descrA** – matrix descriptor for input matrix *A*
- **csrValA** – nonzero values of matrix
- **csrRowPtrA** – row pointers of matrix
- **csrColIndA** – column indices of matrix
- **blockDim** – block dimension of output matrix *C*
- **descrC** – matrix descriptor for output matrix *C*
- **bsrValC** – nonzero values of output matrix *C*
- **bsrRowPtrC** – block row pointers of output matrix *C*
- **bsrColIndC** – block column indices of output matrix *C*

Returns number of nonzeros of matrix

`accelerate.cuda.sparse.Sparse.Xcsr2coo` (*csrRowPtr, nnz, m, cooRowInd*)

Converts an array of compressed row pointers corresponding to the CSR format into an array of uncompressed row indices corresponding to the COO format.

Parameters

- **csrRowPtr** – vector of row pointers
- **nnz** – number of nonzeros
- **m** – number of rows of matrix
- **cooRowInd** – vector of uncompressed row indices written by this function

Returns None

`accelerate.cuda.sparse.Sparse.csr2csc` (*m, n, nnz, csrVal, csrRowPtr, csrColInd, cscVal, cscRowInd, cscColPtr, copyValues*)

Converts a sparse matrix in CSR format into a sparse matrix in CSC format.

Parameters

- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **nnz** – number of nonzeros of the matrix
- **csrVal** – values in the CSR representation
- **csrRowPtr** – row indices in the CSR representation
- **csrColInd** – column pointers in the CSR representation

- **cscVal** – values in the CSC representation
- **cscRowInd** – row indices in the CSC representation
- **cscColPtr** – column pointers in the CSC representation
- **copyValues** – ‘N’ or ‘S’ for symbolic or numeric copy of values

Returns None

`accelerate.cuda.sparse.Sparse.csr2dense(m, n, descr, csrVal, csrRowPtr, csrColInd, A, lda)`
 Convert a sparse matrix in CSR format into dense format.

Parameters

- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **descr** – matrix descriptor
- **csrVal** – values in the CSR representation
- **csrRowPtr** – row indices in the CSR representation
- **csrColInd** – column pointers in the CSR representation
- **A** – the dense representation, written to by this function
- **lda** – leading dimension of the matrix

Returns None

`accelerate.cuda.sparse.Sparse.dense2csc(m, n, descrA, A, lda, nnzPerCol, cscVal, cscRowInd, cscColPtr)`

Convert a dense matrix into a sparse matrix in CSC format. The *nnzPerCol* parameter may be computed with a call to `nnz()`.

Parameters

- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **descrA** – matrix descriptor
- **A** – the matrix in dense format
- **lda** – leading dimension of the matrix
- **nnzPerCol** – array containing the number of nonzero elements per column
- **cscVal** – values in the CSC representation
- **cscRowInd** – row indices in the CSC representation
- **cscColPtr** – column pointers in the CSC representation

Returns None

`accelerate.cuda.sparse.Sparse.dense2csr(m, n, descrA, A, lda, nnzPerRow, csrVal, csrRowPtr, csrColInd)`

Convert a dense matrix into a sparse matrix in CSR format. The *nnzPerRow* parameter may be computed with a call to `nnz()`.

Parameters

- **m** – number of rows of matrix
- **n** – number of columns of matrix

- **descrA** – matrix descriptor
- **A** – the matrix in dense format
- **lda** – leading dimension of the matrix
- **nnzPerRow** – array containing the number of nonzero elements per row
- **csrVal** – values in the CSR representation
- **csrRowPtr** – row indices in the CSR representation
- **csrColInd** – column pointers in the CSR representation

Returns None

`accelerate.cuda.sparse.Sparse.nnz(dirA, m, n, descrA, A, lda, nnzPerRowCol)`

Computes the number of nonzero elements per row or column of a dense matrix, and the total number of nonzero elements in the matrix.

Parameters

- **dirA** – ‘R’ for the number of nonzeros per row, or ‘C’ for per column.
- **m** – number of rows of matrix
- **n** – number of columns of matrix
- **descrA** – matrix descriptor
- **A** – the matrix
- **lda** – leading dimension of the matrix
- **nnzPerRowCol** – array to contain the number of nonzeros per row or column

Returns total number of nonzeros in the matrix

cuFFT

Provides FFT and inverse FFT for 1D, 2D and 3D arrays. See [NVIDIA cuFFT](#).

Note: cuFFT only supports FFT operations on `numpy.float32`, `numpy.float64`, `numpy.complex64`, `numpy.complex128` with C-contiguous datalayout.

Forward FFT

`accelerate.cuda.fft.fft(ary, out[, stream])`

`accelerate.cuda.fft.fft_inplace(ary[, stream])`

Parameters

- **ary** – The input array. The inplace version stores the result in here.
- **out** – The output array for non-inplace versions.
- **stream** – The CUDA stream in which all operations will take place.

Inverse FFT

```
accelerate.cuda.fft.ifft(ary, out[, stream])  
accelerate.cuda.fft.ifft_inplace(ary[, stream])
```

Parameters

- **ary** – The input array. The inplace version stores the result in here.
- **out** – The output array for non-inplace versions.
- **stream** – The CUDA stream in which all operations will take place.

FFTPlan

cuRAND

Provides *pseudo-random number generator* (PRNG) and *quasi-random generator* (QRNG). See [NVIDIA cuRAND](#).

CUDA Sorting

Accelerate provides routines for sorting arrays on CUDA GPUs.

Sorting Large Arrays

The `accelerate.cuda.sorting.RadixSort` class is recommended for sorting large (approx. more than 1 million items) arrays of numeric types.

Sorting Many Small Arrays

Using `accelerate.cuda.sorting.RadixSort` on small (approx. less than 1 million items) arrays has significant overhead due to multiple kernel launches.

A better alternative is to use `accelerate.cuda.sorting.segmented_sort()` -which launches a single kernel for sorting a batch of many small arrays.

Math Kernel Library

The Math Kernel Library provides BLAS, LAPACK, and other math routines. For more information, see [Intel's site](#).

The following functions, FFT variants and accelerated UFuncs are available for use with Accelerate:

MKL utility functions

The `accelerate.mkl` module contains a set of functions to configure and retrieve information about the underlying Intel MKL library.

Reference

`accelerate.mkl.set_num_threads(n)`

Set the number of threads Intel MKL should use. This is only a hint, and no guarantee is made this number of threads will actually be used. This function takes precedence over the environment variable `MKL_NUM_THREADS`.

This function wraps the Intel MKL function `mkl_set_num_threads`.

`accelerate.mkl.get_max_threads()` → int

Return the number of threads Intel MKL is targeting for parallelism.

This function wraps the Intel MKL function `mkl_get_max_threads`.

`accelerate.mkl.get_version_string()` → str

Return the Intel MKL version information as a string.

This function wraps the Intel MKL function `mkl_get_version_string`.

`accelerate.mkl.mem_stat()` → int, int

Return a (bytes, blocks) tuple of memory usage statistics about the underlying Intel MKL memory allocator. The return tuple contains:

- The total number of bytes allocated (bytes).
- The number of allocated blocks (blocks).

This function wraps the Intel MKL function `mkl_mem_stat`.

`accelerate.mkl.get_cpu_clocks()` → int

Return elapsed CPU clocks as an integer. This may be useful when timing short intervals with high resolution. Note the result is limited to unsigned 64 bit integers, so wrapping of elapsed time is possible.

This function wraps the Intel MKL function `mkl_get_cpu_clocks`.

`accelerate.mkl.get_cpu_frequency()` → int

Return CPU frequency in GHz as a float. Note the result may vary from run to run as it returns the current frequency. That frequency can change in some systems due to several factors (i.e. power management).

This function wraps the Intel MKL function `mkl_get_cpu_frequency`.

MKL BLAS functions

The `accelerate.mkl.blas` module contains a subset of BLAS functions implemented by means of the underlying Intel MKL library.

Reference

`accelerate.mkl.blas.dot(x, y)`

Compute and return the vector dot product of *x* and *y*.

Parameters

- **x** – one-dimensional array
- **y** – one-dimensional array

Return type

 result

Note the input arguments may be copied to adjust their types.

Example

```
alpha = 1.+1.j
A = np.arange(16, dtype=np.float64).reshape(4,4)
x = np.arange(4, dtype=np.float64)
beta = 0.
y = np.arange(4, dtype=np.float64)
result = blas.gemv('N', alpha, A, x, beta, y)
```

MKL FFT

The speed-boosted variants of NumPy's FFT operations are accessible in the `numpy.fft` package, and the `accelerate.mkl.fftpack` package. The following functions in these packages are accelerated using MKL:

Function	Description
<code>fft(a, n=None, axis=-1)</code>	1-dimensional forward transform
<code>ifft(a, n=None, axis=-1)</code>	1-dimensional inverse transform
<code>rfft(a, n=None, axis=-1)</code>	1-dimensional forward transform of purely real data
<code>irfft(a, n=None, axis=-1)</code>	1-dimensional inverse transform of purely real data
<code>hfft(a, n=None, axis=-1)</code>	Hermite transform
<code>ihfft(a, n=None, axis=-1)</code>	Inverse Hermite transform
<code>fftn(a, s=None, axes=None)</code>	N-dimensional forward transform
<code>ifftn(a, s=None, axes=None)</code>	N-dimensional inverse transform
<code>fft2(a, s=None, axes=(-2, -1))</code>	2-dimensional forward transform
<code>ifft2(a, s=None, axes=(-2, -1))</code>	2-dimensional inverse transform
<code>rfftn(a, s=None, axes=None)</code>	N-dimensional forward transform of purely real data
<code>rfft2(a, s=None, axes=(-2, -1))</code>	2-dimensional forward transform of purely real data
<code>irfftn(a, s=None, axes=None)</code>	N-dimensional inverse transform of purely real data
<code>irfft2(a, s=None, axes=(-2, -1))</code>	2-dimensional inverse transform of purely real data

For further information on these functions, please refer to the Numpy documentation: `numpy.fft`.

Accelerated UFuncs

Variants of some Numpy UFuncs that use Intel's Vector Math Library (VML) are found in the `accelerate.mkl` package in the `ufuncs` object. In comparison to Numpy's built-in UFuncs, Accelerated UFuncs have the following properties:

Performance Because Accelerated UFuncs call functions from VML, which is a library optimised for high performance using multiple threads and SIMD instructions, performance may be increased when calling Accelerated UFuncs in comparison to calling Numpy UFuncs. The performance increase will only be obtained for contiguous arguments. For non-contiguous arguments, performance comparable to Numpy's will be observed.

Accuracy

- Accelerated UFuncs produce similar results to their Numpy equivalents for the range of finite values, up to a given relative tolerance.
- The tolerance varies between functions and data types, and is specified for each combination in the following section.
- For the range of infinite and NaN values, the majority of results computed by Accelerated UFuncs will be equal to those computed by their Numpy counterparts. However, this is not guaranteed; for example, an

input for which the Numpy UFunc produces a result of $x + \text{inf} \cdot j$, the equivalent Accelerated UFunc may produce a result of $y + \text{inf} \cdot j$, where $x \neq y$.

- Towards the edge of the domain of a data type (e.g. near $3.4\text{e}+38$ for `float` and $1.79\text{e}+308$ for `double` and values of similar magnitude at the negative end of the domain) some Accelerated UFuncs may produce results which differ from Numpy UFuncs, or may raise `FloatingPointError` or `ZeroDivisionError` exceptions. These functions are marked *domain edge warning* in the *Accuracy* column of the tables in the following sections.
- Some numpy implementations of functions that operate in the complex domain have branch cuts which differ from those in MKL, where this has been identified in testing these functions are marked *branch cut warning* in the *Accuracy* column of the tables in the following sections. This warning may also be present in the case of implementations which contain incorrect branch cuts.
- Denormal input values may be treated as zero by Accelerated UFuncs, and denormal output values may be flushed to zero.
- The accuracy reported is approximate and related to the least accurate value encountered when testing with contiguous input arguments. Non-contiguous arguments are more directly exposed to system math library implementations and so their accuracy is not commented on.

Exception handling For the range of finite values, exceptions will not be raised by Accelerated UFuncs, just as they would not by Numpy. For the infinite and NaN ranges, Accelerated UFuncs may raise `FloatingPointError` or `ZeroDivisionError` exceptions in cases when Numpy would not, and vice-versa.

Supported functions are described in the following sections.

Arithmetic Functions

Function	Type	Accuracy
add(x, y)	f4	rtol=1.0e-7
	f8	rtol=1.0e-15
	c8	rtol=1.0e-7
	c16	rtol=1.0e-15
subtract(x, y)	f4	rtol=1.e-7
	f8	rtol=1.e-15
	c8	rtol=1.e-7
	c16	rtol=1.e-15
square(x)	f4	rtol=1.e-7
	f8	rtol=1.e-15
multiply(x, y)	f4	rtol=1.e-7
	f8	rtol=1.e-15
	c8	rtol=1.e-6
	c16	rtol=1.e-15
absolute(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15

Power and Root Functions

Function	Type	Accuracy
reciprocal(x)	f4	rtol=1.e-7
	f8	rtol=1.e-15
true_divide(x, y)	f4	rtol=1.e-7
	f8	rtol=1.e-15
	c8	rtol=1.e-6
	c16	rtol=1.e-15
sqrt(x, y)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
power(x, y)	f4	rtol=1.e-7
	f8	rtol=1.e-15
hypot(x, y)	f4	rtol=1.e-6
	f8	rtol=1.e-15

Exponential and Logarithmic Functions

Function	Type	Accuracy
exp(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
expm1(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
log(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-5
	c16	rtol=1.e-13
log10(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-5, domain edge warning
	c16	rtol=1.e-13, domain edge warning
log1p(x)	f4	rtol=1.e-6
	f8	rtol=1.e-15

Trigonometric Functions

Function	Type	Accuracy
cos (x)	f4	rtol=1.e-6, domain edge warning
	f8	rtol=1.e-15, domain edge warning
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
sin (x)	f4	rtol=1.e-5, domain edge warning
	f8	rtol=1.e-15, domain edge warning
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
tan (x)	f4	rtol=1.e-6, domain edge warning
	f8	rtol=1.e-15, domain edge warning
	c8	rtol=5.e-4, domain edge warning
	c16	rtol=5.e-14, domain edge warning
arccos (x)	f4	rtol=1.e-6, branch cut warning
	f8	rtol=1.e-15, branch cut warning
	c8	rtol=1.e-5, domain edge warning, branch cut warning
	c16	rtol=1.e-14, domain edge warning, branch cut warning
arcsin (x)	f4	rtol=1.e-6, branch cut warning
	f8	rtol=1.e-15, branch cut warning
	c8	rtol=1.e-3, domain edge warning, branch cut warning
	c16	rtol=1.e-12, domain edge warning, branch cut warning
arctan (x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-6
	c16	rtol=1.e-15
arctan2 (x)	f4	rtol=1.e-6
	f8	rtol=1.e-15

Hyperbolic Functions

Function	Type	Accuracy
cosh (x)	f4	rtol=1.e-6, domain edge warning
	f8	rtol=1.e-15, domain edge warning
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
sinh (x)	f4	rtol=1.e-6, domain edge warning
	f8	rtol=1.e-15, domain edge warning
	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning

	c8	rtol=1.e-6, domain edge warning
	c16	rtol=1.e-15, domain edge warning
arccosh (x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=1.e-5, domain edge warning
	c16	rtol=1.e-14, domain edge warning
arcsinh (x)	f4	rtol=1.e-6
	f8	rtol=1.e-15
	c8	rtol=5.e-5, domain edge warning
	c16	rtol=1.e-13, domain edge warning
arctanh (x)	f4	rtol=1.e-5, branch cut warning
	f8	rtol=5.e-11, branch cut warning
	c8	rtol=1.e-4, domain edge warning, branch cut warning
	c16	rtol=5.e-14, domain edge warning, branch cut warning

Profiling

The Python standard library includes code profiling functionality. When active, function invocations and the time spent on them are recorded.

The `accelerate.profiler` module extends this functionality by also recording the functions' signatures, which are useful because often the precise control flow—and thus function performance—depends on the argument types. For NumPy array types, this includes not only the `dtype` attribute, but also the array's shape.

Profiling example

The following code defines a simple dot function and profiles it without signatures to match the behaviour of the Python standard library profile module:

```
from accelerate import profiler
import numpy as np

def dot(a, b):
    sum=0
    for i in range(len(a)):
        sum += a[i]*b[i]
    return sum

a = np.arange(16, dtype=np.float32)
b = np.arange(16, dtype=np.float32)

p = profiler.Profile(signatures=False)
p.enable()
dot(a, b)
p.disable()
p.print_stats()
```

This generates the following output:

```
3 function calls in 0.000 seconds

Ordered by: standard name

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1      0.000    0.000    0.000    0.000 builtins.len
1      0.000    0.000    0.000    0.000 dot.py:7(dot)
1      0.000    0.000    0.000    0.000 {method 'disable' of 'prof.Profiler'
↳objects}
```

NOTE: By default, the Profile constructor's signature flag is set to True, resulting in the following output:

```
3 function calls (2 primitive calls) in 0.000 seconds

Ordered by: standard name

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1      0.000    0.000    0.000    0.000 dot.py:1(disable())
2/1     0.000    0.000    0.000    0.000 dot.py:7(dot(a:ndarray(dtype=float32,
↳shape=(16,)), b:ndarray(dtype=float32, shape=(16,)))
```

In the results for more realistic code, the call graph—and thus the table of function calls—is much bigger, making working with data in tabular form inconvenient.

To solve this, the `accelerate.profiler` module also provides functionality to visualize the data. Instead of calling the `print_stats()` method, call the `accelerate.profiler.plot()` function.

NOTE: At this time, the `accelerate.profiler.plot()` function may only be called from inside a notebook.

If the code above was executed from inside a notebook, run the following code:

```
In [3]: profiler.plot(p)
```

Which generates the following output:

Accelerate.profiler API

Environment variables

ACCELERATE_WARNINGS

If set to anything but 0 (zero), Accelerate may issue performance warnings, such as when input arguments need to be copied to adjust their data layout, or types, to match particular backend requirements.

License agreement

Anaconda Accelerate End User License Agreement

Anaconda Accelerate (“the Software Product” or “Accelerate”) and accompanying documentation is licensed and not sold. The Software Product is protected by copyright laws and treaties, as well as laws and treaties related to other forms of intellectual property. Continuum Analytics, Inc. (dba Anaconda, Inc.) or its subsidiaries, affiliates, and suppliers (collectively “Continuum”) own intellectual property rights in the Software Product. The Licensee’s (“you” or “your”) license to download, use, copy, or change the Software Product is subject to these rights and to all the terms and conditions of this End User License Agreement (“Agreement”).

Acceptance

YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS AGREEMENT BY SELECTING THE “ACCEPT” OPTION AND DOWNLOADING THE SOFTWARE PRODUCT OR BY INSTALLING, USING, OR COPYING THE SOFTWARE PRODUCT. YOU MUST AGREE TO ALL OF THE TERMS OF THIS AGREEMENT BEFORE YOU WILL BE ALLOWED TO DOWNLOAD THE SOFTWARE PRODUCT. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, YOU MUST SELECT “DECLINE” AND YOU MUST NOT INSTALL, USE, OR COPY THE SOFTWARE PRODUCT.

Other Vendor Tools

In addition to Continuum’s proprietary software, the Software product may contain other software packages from other sources (“Other Vendor Tools”). These are available on an “as is” basis and subject to their individual license agreements. These licenses are available either in the package distributed with the Software Product or via request to info@anaconda.com. Any binary packages of Other Vendor Tools you obtain via Accelerate are subject to their individual licenses as well as the terms of this EULA. Continuum reserves the right to change which Other Vendor Tools are provided in Accelerate.

Trial Period

You have the right to use Accelerate on a single computer or group of computers for 30 days with no license. After 30 days you must purchase an appropriate license to use the software on one or more machines or stop using the software and remove it from all of your machines on which you installed the software.

License Grant

This Agreement entitles you to install and use one copy of the Software Product on as many machines as you will personally use. The Software Product is licensed to a particular user. Only the user to whom the software is licensed may use the software. You must obtain a license for as many users as you wish to use the software. In addition, you may make archival copies of the Software Product Installer.

Right to Updates

This license entitles you to updates to the Software Product for one year from the time of payment. The Software Product will continue to function and you may continue to use The Software Product and any updates you have received for as long as you would like however you will no longer be able to receive updates from Continuum unless this License is renewed. Please contact sales@anaconda.com with any questions or concerns.

Restrictions on Transfer

Without first obtaining the express written consent of Continuum, you may not assign your rights and obligations under this Agreement, or redistribute, encumber, sell, rent, lease, sublicense, or otherwise transfer your rights to the Software Product.

Restrictions on Use

You may not use, copy, or install the Software Product on any system where more than one user will be able to use the software unless you have purchased a license for each user of the system. You may not decompile, “reverse-engineer”, disassemble, or otherwise attempt to derive the source code for the Software Product.

Restrictions on Alteration

You may not modify the Software Product or create any derivative work of the Software Product or its accompanying documentation. Derivative works include but are not limited to translations. You may not alter any files or libraries in any portion of the Software Product.

Restrictions on Copying

You may not copy any part of the Software Product except to the extent that licensed use inherently demands the creation of a temporary copy stored in computer memory and not permanently affixed on storage medium. You may make archival copies of the Software Product installer.

Limited Software Product Warranty

For a period of 60 days from the date of shipment or from the date that you download the Software Product, as applicable, Continuum warrants that when properly installed and used under normal conditions, the Software Product will perform substantially as advertised.

Disclaimer of Warranties and Limitation of Liability

UNLESS OTHERWISE EXPLICITLY AGREED TO IN WRITING BY CONTINUUM, CONTINUUM MAKES NO OTHER WARRANTIES, EXPRESS OR IMPLIED, IN FACT OR IN LAW, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE OTHER THAN AS SET FORTH IN THIS AGREEMENT OR IN THE LIMITED WARRANTY DOCUMENTS PROVIDED WITH THE SOFTWARE PRODUCT.

Continuum makes no warranty that the Software Product will meet your requirements or operate under your specific conditions of use. Continuum makes no warranty that operation of the Software Product will be secure, error free, or free from interruption. YOU MUST DETERMINE WHETHER THE SOFTWARE PRODUCT SUFFICIENTLY MEETS YOUR REQUIREMENTS FOR SECURITY AND UNINTERRUPTABILITY. YOU BEAR SOLE RESPONSIBILITY AND ALL LIABILITY FOR ANY LOSS INCURRED DUE TO FAILURE OF THE SOFTWARE PRODUCT TO MEET YOUR REQUIREMENTS. CONTINUUM WILL NOT, UNDER ANY CIRCUMSTANCES, BE RESPONSIBLE OR LIABLE FOR THE LOSS OF DATA ON ANY COMPUTER OR INFORMATION STORAGE DEVICE. UNDER NO CIRCUMSTANCES SHALL CONTINUUM, ITS DIRECTORS, OFFICERS, EMPLOYEES OR AGENTS BE LIABLE TO YOU OR ANY OTHER PARTY FOR INDIRECT, CONSEQUENTIAL,

SPECIAL, INCIDENTAL, PUNITIVE, OR EXEMPLARY DAMAGES OF ANY KIND (INCLUDING LOST REVENUES OR PROFITS OR LOSS OF BUSINESS) RESULTING FROM THIS AGREEMENT, OR FROM THE FURNISHING, PERFORMANCE, INSTALLATION, OR USE OF THE SOFTWARE PRODUCT, WHETHER DUE TO A BREACH OF CONTRACT, BREACH OF WARRANTY, OR THE NEGLIGENCE OF CONTINUUM OR ANY OTHER PARTY, EVEN IF CONTINUUM IS ADVISED BEFOREHAND OF THE POSSIBILITY OF SUCH DAMAGES. TO THE EXTENT THAT THE APPLICABLE JURISDICTION LIMITS CONTINUUM'S ABILITY TO DISCLAIM ANY IMPLIED WARRANTIES, THIS DISCLAIMER SHALL BE EFFECTIVE TO THE MAXIMUM EXTENT PERMITTED.

Limitation of Remedies and Damages

Your remedy for a breach of this Agreement or of any warranty included in this Agreement is the correction or replacement of the Software Product. Selection of whether to correct or replace shall be solely at the discretion of Continuum. Continuum reserves the right to substitute a functionally equivalent copy of the Software Product as a replacement. If Continuum is unable to provide a replacement or substitute Software Product or corrections to the Software Product, your sole alternate remedy shall be a refund of the purchase price for the Software Product exclusive of any costs for shipping and handling. Any claim must be made within the applicable warranty period. All warranties cover only defects arising under normal use and do not include malfunctions or failure resulting from misuse, abuse, neglect, alteration, problems with electrical power, acts of nature, unusual temperatures or humidity, improper installation, or damage determined by Continuum to have been caused by you. All limited warranties on the Software Product are granted only to you and are non-transferable. You agree to indemnify and hold Continuum harmless from all claims, judgments, liabilities, expenses, or costs arising from your breach of this Agreement and/or acts or omissions.

Governing Law, Jurisdiction and Costs

This Agreement is governed by the laws of Texas, without regard to Texas's conflict or choice of law provisions.

Export Regulations

Any use or distribution of Accelerate is made under conditions that the user and/or distributor is in full compliance with all export and other governing laws of the United States of America, including full and ongoing compliance with the Export Administration Regulations (EAR) of the United States Department of Commerce. See www.commerce.gov/ and <http://www.bis.doc.gov/index.php/regulations/export-administration-regulations-ear>. Use or distribution of Continuum software products to any persons, entities or countries currently under US sanctions is strictly prohibited. Accelerate is classified with an ECCN of 5D992 with no license required for export to non-embargoed countries.

The United States currently has embargoes against Cuba, Iran, North Korea, Sudan and Syria. The exportation, re-exportation, sale or supply, directly or indirectly, from the United States, or by a U.S. person wherever located, of any Continuum software to any of these countries is strictly prohibited without prior authorization by the United States Government. By accepting this Agreement, you represent to Continuum that you will comply with all applicable export regulations for Accelerate.

Severability

If any provision of this Agreement shall be held to be invalid or unenforceable, the remainder of this Agreement shall remain in full force and effect. To the extent any express or implied restrictions are not permitted by applicable laws, these express or implied restrictions shall remain in force and effect to the maximum extent permitted by such applicable laws.

Release notes

Release notes

Version 2.3.1

This is a minor update to bump the required version of Numba to 0.30 and to support Python 3.6.

Version 2.3.0

This release of Accelerate is a feature release, containing these additions:

- A new BLAS wrapper API on top of MKL.
- MKL 11.3.3 is now supported.
- Numba 0.26 is supported-and is required.

Version 2.2.0

This release of Accelerate is a feature release, containing two additions:

- Expanded the support of Intel MKL accelerated ufuncs with trigonometric and hyperbolic functions.
- Numba 0.25 is supported, and is a requirement.

Version 2.1.0

This release of Accelerate is a feature release, containing 2 additions:

- Profiling tools
 - An enhanced version of the Python profiler that captures function arguments, including shapes and dtypes of Numpy arrays.
 - Integration of tools for visualising profiles in Jupyter notebooks, allowing interactive experimentation.
- Accelerated UFuncs, which provide a speed improvement over Numpy's built-in UFuncs by using Intel MKL.

Version 2.0.2

This update adds support for updated versions of Numba and MKL:

- Numba 0.23 is now supported, and is a requirement.
- MKL 11.3.1, standard in Anaconda 2.5, is now supported.

Version 2.0.1

This minor update to Accelerate adds no functional changes, but provides additional clarification of the the relationship between the Accelerate and NumbaPro conda packages upon installation.

Version 2.0

NumbaPro has been deprecated, and its code generation features have been moved into open-source Numba. The CUDA library functions have been moved into Accelerate, along with some Intel MKL functionality. High-level functions and access to additional native library implementations will be added in future releases of Accelerate, and there will be no further updates to NumbaPro.

A NumbaPro compatibility layer (listed as release 0.22.0 of NumbaPro) provides access to the new Accelerate packages through the old NumbaPro package names. This avoids the need to change any existing code immediately for use with Accelerate. A warning will be generated upon import of the compatibility layer, to highlight the deprecation of the NumbaPro package.

CUDA libraries

CUDA library functionality is equivalent to that in NumbaPro 0.21, with the following packages renamed:

NumbaPro Package	Accelerate package
<code>numbapro.cudalib.cublas</code>	<code>accelerate.cuda.blas</code>
<code>numbapro.cudalib.cuffft</code>	<code>accelerate.cuda.fft</code>
<code>numbapro.cudalib.curand</code>	<code>accelerate.cuda.rand</code>
<code>numbapro.cudalib.cusparse</code>	<code>accelerate.cuda.sparse</code>
<code>numbapro.cudalib.sorting</code>	<code>accelerate.cuda.sorting</code>

Code generation

The `vectorize` targets `parallel` and `cuda` can now be accessed with Numba, as can the `cuda.reduce` decorator. Printing of integers and floating point values from CUDA kernels is also possible in Numba, and no longer requires NumbaPro or Accelerate to be imported.

Intel MKL

The MKL FFT implementation is available in the package `accelerate.mkl.fftpack`, and MKL service functions are available in the `accelerate.mkl` package.

The following documentation is provided for users who have not yet upgraded to the current version:

4.4.2 Anaconda Adam

Server & Cluster Installer & Manager

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it.

Anaconda Adam is a command line interface (CLI) utility for Linux that lets you:

- Install and manage these Anaconda® platform components:

Platform component	Description
Anaconda Enterprise Notebooks	Collaborative multi-user notebooks and projects
Anaconda Repository	On-premise repository for conda packages and environments
Anaconda Scale	Distributed package management and computation framework

- Create, provision and remove clusters.

- Perform administration tasks on Amazon Elastic Compute Cloud (EC2) servers.
- Manage Anaconda packages.
- Execute commands on multiple nodes.

You must have an [Anaconda Enterprise](#) license to install Anaconda platform components. If you would like to purchase Anaconda platform, please contact sales@anaconda.com.

You can use Adam with:

- Distributed computation frameworks such as Spark or Dask.
- Enterprise Hadoop distributions such as Cloudera CDH or Hortonworks HDP.
- HPC clusters.
- A collection of virtual machines or containers.

Installation

Installation requirements

Make sure your system meets the requirements below before installing and using Anaconda Adam.

Hardware and operating system

To install Adam, you must have one or more 64-bit Linux machines with one of the following Linux distributions:

- RHEL/CentOS 6 or 7
- Ubuntu 14.04 or 16.04

and the following commands installed:

- `ssh`
- `openssl`
- `curl`
- `md5sum`

License

To install Adam, you must have a valid [Anaconda Enterprise](#) license.

Account access and security

To install Adam, you need one of the following access options on the target machines:

- Access to the root user with the root password.
- Access to the root user with an SSH key pair.
- Passwordless SSH/sudo enabled for a user account.
- Password-based SSH and passwordless sudo enabled for a user account.

The root or user credentials used for installation must be the same on all of the target nodes.

Network

You must configure network and security settings to allow access to and from each node—for example, using IPTables or SELinux.

Anaconda platform components use the default network ports listed below. You can configure these ports when you define a cluster profile.

Platform Component	Port
Anaconda Adam (SSH)	22
Anaconda Adam (Salt)	14505
Anaconda Adam (Salt)	14506
Anaconda Adam (Salt REST API)	18000
Anaconda Enterprise Notebooks (UI)	80
Anaconda Enterprise Notebooks (Gateway)	8089
Anaconda Repository (UI)	8080
Anaconda Scale (Dask/Distributed)	8786
Anaconda Scale (Dask/Distributed UI)	8787
Anaconda Scale (Jupyter Notebook UI)	8888

Network ports with a browser user interface (UI) must be accessible by machines outside of the network of Anaconda platform nodes.

Network ports without a browser UI must be accessible between the other Anaconda platform nodes.

Platform components

See the documentation below for information on CPU, memory and disk space requirements for Anaconda platform components.

- [Anaconda Enterprise Notebooks](#).
- [Anaconda Repository](#).
- [Anaconda Scale](#).

Python considerations

Adam and Anaconda platform components do not affect existing framework installations of Python. Adam operates independently from the system installation of Python, while Anaconda platform components install their own versions of Python via Anaconda or Miniconda.

Standard installation

Downloading the Adam installer

To download the installer, run one of the commands below on the host machine where you want to manage the Anaconda platform:

```
wget https://anaconda.org/anaconda-adam/adam-installer/4.4.0/download/adam-installer-4.4.0-Linux-x86_64.sh
```

Or:

```
curl -LO https://anaconda.org/anaconda-adam/adam-installer/4.4.0/download/adam-installer-4.4.0-Linux-x86_64.sh
```

Installing Adam

1. Run the installer, specifying the installation directory:

```
bash adam-installer-4.4.0-Linux-x86_64.sh -b -p ~/adam
```

NOTE: Replace ~/adam with the actual installation directory.

2. Add the adam command to your path by modifying the ~/.bashrc file:

```
echo -e '\n# Anaconda Adam\nexport PATH=~/.adam/bin:$PATH' >> ~/.bashrc
```

3. To activate the changes, source your ~/.bashrc file:

```
source ~/.bashrc
```

Verifying the installation

To verify that the installation succeeded and to create configuration files in ~/.continuum/adam, run the adam command, which outputs the Adam help text:

```

$ adam
Usage: adam [OPTIONS] COMMAND [ARGS]...

Options:
  --version            Show the version and exit.
  -l, --log-level [info|debug|error]
                        Logging level [default: debug]
  -h, --help           Show this message and exit.

Commands:
  cmd                Execute a command on the nodes
  describe           Describe an Adam cluster or profile
  ec2                EC2 options
  enterprise-notebooks
                    Anaconda Enterprise Notebooks options
  info              Display Adam version, system, and
                    license information
  jupyter           Jupyter options
  kubernetes        Kubernetes options
  list              List Adam clusters and profiles
  platform          Anaconda Platform options
  provision         Provision options
  remove            Remove a cluster
  repository        Anaconda Repository options
  salt              Execute a Salt module
  scale             Anaconda Scale options
  ssh               SSH to one of the nodes (0-based
                    index)
  up                Create a cluster from a profile

```

Installing your Anaconda Enterprise license file

Copy your Anaconda Enterprise license file to any of the following directories:

- `~/adam/licenses/`.
- `~/continuum/`.
- Any other directory shown by the command `~/adam/bin/conda info --license`.

Adam searches all of these directories for license files named `license*.txt`.

EXAMPLE: `~/adam/licenses/license_bundle_20170428044737.txt`.

Defining a cluster profile

1. Switch to root user and create a file with this name and path `~/continuum/adam/profile.d/profile.yaml` and the following contents:

```

name: profile
provider: bare

bare:
  username: centos
  \# password: password \# Optional
  port: 22
  keypair: ~/.ssh/my-private-key

```

(continues on next page)

(continued from previous page)

```

nodes:
- host: node1.company.com
- host: node2.company.com
- host: node3.company.com
- host: node4.company.com

security:
flush_iptables: false
selinux_context: false
selinux_permissive: false

```

2. Replace `centos` with an actual username. Verify that the username has `sudo` privileges.
3. Replace `22` with the appropriate *SSH port number*.
4. Replace `~/.ssh/my-private-key` with the location of the private SSH key (key pair) to be used. Verify that you have SSH access to all of the cluster nodes.
5. Edit the IP addresses or hostnames of the nodes in the cluster. Each host must be able to connect to the other hosts using the specified FQDN or IP address.

TIP: We recommend using the nodes' FQDN that matches the hostname on each machine.

NOTE: The first node in the list of nodes is the head node. The remaining nodes are compute nodes.

By default, the `anaconda` user/group is created across the cluster and owns the directory and files located in the root installation directory. If desired, you can *customize the cluster profile* to change these and other settings.

Creating a cluster

To create a cluster, run:

```
adam up -n [cluster-name] [profile-name]
```

EXAMPLE: To create a cluster named “cluster” from a cluster profile named “profile”:

```
adam up -n cluster profile
```

Installing platform components

After creating or *provisioning a cluster*, you can install platform components by running:

```
adam [platform-component] -n [cluster-name] install
```

EXAMPLE: To install Repository, Enterprise Notebooks, and Scale on a cluster named “cluster”:

```

$ adam repository -n cluster install
$ adam enterprise-notebooks -n cluster install
$ adam scale -n cluster cluster install
$ adam scale -n cluster dask install

```

Opening a platform component

To open a platform component’s user interface in your browser, run:

```
$ adam [platform-component] -n [cluster-name] open
```

EXAMPLE: To open Repository and Enterprise Notebooks on a cluster named “cluster”:

```
$ adam repository -n cluster open
$ adam enterprise-notebooks -n cluster open
```

For more information see *Working with platform components*.

Installing into an air gapped environment

Currently, Adam can install the remote conda management functionality in an *air gapped* environment using artifacts from Repository. In future versions of Adam, air gapped installations of all Anaconda platform components will be fully supported.

1. *Install Repository*.
2. Configure Repository for the Adam installation on the nodes:
 1. Mirror the `anaconda` and `anaconda-adam` channels onto your local Repository.
 2. Copy the latest versions of the [Anaconda](#) and [Miniconda](#) installers to the `/static/extras/` folder on the Repository web server.
3. Switch to root user and create a cluster profile at `~/.continuum/adam/profile.d/profile.yaml` with the following contents:

```
name: profile
provider: bare

bare:
  username: centos
  # password: password # Optional
  port: 22
  keypair: ~/.ssh/my-private-key
  nodes:
    - host: node1.company.com
    - host: node2.company.com
    - host: node3.company.com
    - host: node4.company.com

plugins:
  conda:
    anaconda_hash: md5=d72add23bc937ccdfc7de4f47deff843
    anaconda_url: http://local.anaconda.repository.address:8080/static/extras/
    ↪Anaconda2-4.4.0-Linux-x86_64.sh
    channel_alias: http://local.anaconda.repository.address:8080/conda/
    channels:
      - http://local.anaconda.repository.address:8080/conda/anaconda
      - http://local.anaconda.repository.address:8080/conda/anaconda-adam
    enabled: true
    miniconda_hash: md5=7097150146dd3b83c805223663ebffcc
    miniconda_url: http://local.anaconda.repository.address:8080/static/extras/
    ↪Miniconda2-4.3.21-Linux-x86_64.sh
    rootdir: /opt/continuum
    ssl_verify: False
```

(continues on next page)

(continued from previous page)

```
security:
  flush_iptables: false
  selinux_context: false
  selinux_permissive: false
```

4. Replace `centos` with an actual username. Verify that the username has `sudo` privileges.
5. Replace `22` with the appropriate *SSH port number*.
6. Replace `~/ .ssh/my-private-key` with the location of the private SSH key (`keypair`) to be used. Verify that you have SSH access to all of the cluster nodes.
7. Edit the port and IP addresses or hostnames of the nodes in the cluster.
NOTE: The first node in the list of nodes is the head node. The remaining nodes are compute nodes.
8. Replace the `anaconda_hash` value with the hash of your Anaconda installer.
9. Replace the `miniconda_hash` value with the hash of your Miniconda installer.
10. Replace `local.anaconda.repository.address` with the address of your Repository.

Installing into a cloud environment

Adam can be used to create cloud-based instances and install Anaconda platform components on the nodes.

Currently, Adam fully supports Amazon Elastic Compute Cloud (EC2).

To use Adam with instances that already exist on Amazon EC2, or with other cloud providers, follow the *primary installation instructions*.

Refer to the *Installation requirements* page for more information about system requirements, including networking and security requirements.

- *Downloading the Adam installer*
- *Installing Adam*
- *Verifying the installation*
- *Installing your Anaconda Enterprise license file*
- *Creating an EC2 cluster*
- *Installing platform components*
- *Opening a platform component*
- *Removing an EC2 cluster*

Downloading the Adam installer

To download the installer, run one of the commands below on the host machine where you want to manage the Anaconda platform:

```
wget https://anaconda.org/anaconda-adam/adam-installer/4.4.0/download/adam-installer-
↳ 4.4.0-Linux-x86_64.sh
```

Or:

```
curl -LO https://anaconda.org/anaconda-adam/adam-installer/4.4.0/download/adam-  
↪installer-4.4.0-Linux-x86_64.sh
```

Installing Adam

1. Run the installer, specifying the installation directory:

```
bash adam-installer-4.4.0-Linux-x86_64.sh -b -p ~/adam
```

NOTE: Replace ~/adam with the actual installation directory.

2. Add the adam command to your path by modifying the ~/.bashrc file:

```
echo -e '\n# Anaconda Adam\nexport PATH=~/adam/bin:$PATH' >> ~/.bashrc
```

3. To activate the changes, source your ~/.bashrc file:

```
source ~/.bashrc
```

Verifying the installation

To verify that the installation succeeded and to create configuration files in ~/.continuum/adam, run the adam command, which outputs the Adam help text:

```
$ adam  
Usage: adam [OPTIONS] COMMAND [ARGS]...  
  
Options:  
  --version                Show the version and exit.  
  -l, --log-level [info|debug|error]  Logging level [default: debug]  
  -h, --help                Show this message and exit.  
  
Commands:  
  cmd                    Execute a command on the nodes  
  describe               Describe an Adam cluster or profile  
  ec2                    EC2 options  
  enterprise-notebooks   Anaconda Enterprise Notebooks options  
  info                   Display Adam version, system, and  
                        license information  
  jupyter                Jupyter options  
  kubernetes             Kubernetes options  
  list                   List Adam clusters and profiles  
  platform               Anaconda Platform options  
  provision               Provision options  
  remove                 Remove a cluster  
  repository             Anaconda Repository options  
  salt                   Execute a Salt module  
  scale                  Anaconda Scale options  
  ssh                    SSH to one of the nodes (0-based  
                        index)  
  up                     Create a cluster from a profile
```

Installing your Anaconda Enterprise license file

Copy your Anaconda Enterprise license file to any of the following directories:

- `~/adam/licenses/`.
- `~/continuum/`.
- Any other directory shown by the command `~/adam/bin/conda info --license`.

Adam searches all of these directories for license files named `license*.txt`.

EXAMPLE: `~/adam/licenses/license_bundle_20170428044737.txt`.

Creating an EC2 cluster

1. Create a file named `~/aws/credentials` that contains your AWS credentials:

```
[default]
aws_access_key_id = your-access-key
aws_secret_access_key = your-secret-key
region = us-east-1
```

NOTE: Replace `your-access-key`, `your-secret-key`, and `us-east-1` with your actual AWS access key ID, your AWS secret access key, and your default region. Region is optional. For more information about configuring your AWS credentials, see the [Boto documentation](#).

2. Create a cluster on EC2 by running:

```
adam ec2 -n mycluster up --keyname my_keypair --keypair ~/.ssh/my_keypair.pem
```

NOTE: Replace “mycluster” with the name you wish to give the new cluster. Replace “my_keypair” with the keyname on the EC2 console. Replace `~/ssh/my_keypair.pem` with the path to the keypair that matches the keyname.

keyname and keypair are required.

OPTIONAL: You can also specify the AMI, number of nodes, instance types and more. To see the available options, run `adam ec2 up --help`:

```
$ adam ec2 -n cluster up --help
Usage: adam ec2 up [OPTIONS]

Options:
  --keyname TEXT           Keyname on EC2 console
                           [required]
  --keypair PATH           Path to the keypair that
                           matches the keyname
                           [required]
  --vpc-id TEXT            EC2 VPC ID
  --subnet-id TEXT         EC2 Subnet ID on the VPC
  --region-name TEXT       AWS region [default:
                           us-east-1]
  --ami TEXT               EC2 AMI [default:
                           ami-d05e75b8]
  --username TEXT          User to SSH to the AMI
                           [default: ubuntu]
  --type TEXT              EC2 Instance Type
```

(continues on next page)

(continued from previous page)

```

                                [default: m4.xlarge]
--count INTEGER                Number of nodes
                                [default: 4]
--security-group TEXT          Security Group Name
                                [default: adam-default]
--volume-type TEXT             Root volume type
                                [default: gp2]
--volume-size INTEGER          Root volume size (GB)
                                [default: 500]
-t, --tag TEXT                 Extra tags to add to the
                                instances
--check-ami / --no-check-ami   Whether or not to check
                                the AMI [default: True]
--provision / --no-provision   Provision salt on the
                                nodes [default: True]
-y, --yes                      Answers yes to questions
-h, --help                     Show this message and exit.
```

Installing platform components

After creating or *provisioning a cluster*, you can install platform components by running:

```
adam [platform-component] -n [cluster-name] install
```

EXAMPLE: To install Repository, Enterprise Notebooks, and Scale on a cluster named “cluster”:

```
$ adam repository -n cluster install
$ adam enterprise-notebooks -n cluster install
$ adam scale -n cluster cluster install
$ adam scale -n cluster dask install
```

Opening a platform component

To open a platform component’s user interface in your browser, run:

```
adam [platform-component] -n [cluster-name] open
```

EXAMPLE: To open Repository and Enterprise Notebooks on a cluster named “cluster”:

```
$ adam repository -n cluster open
$ adam enterprise-notebooks -n cluster open
```

For more information see *Working with platform components*.

Removing an EC2 cluster

To remove an EC2 cluster and terminate the corresponding instances:

1. Run:

```
adam ec2 -n [cluster-name] destroy
```

2. When prompted, type `y`.

EXAMPLE: To remove the cluster named “cluster”:

```
$ adam ec2 -n cluster destroy
Are you sure you want to destroy the cluster cluster?
[y/N]: y
```

The installation process described in the pages above is appropriate for most environments and use cases. However, if you want to customize Anaconda platform settings related to security, network, installation paths, or other settings, please see [Customizing a cluster profile](#).

User guide

Concepts

Anaconda platform components run on clusters, which are groups of machines listed in a cluster profile.

Cluster profile

A cluster profile defines the cluster’s name, its machine nodes and other options such as security and network settings.

One or more cluster profiles are defined during Adam [installation](#), just before creating the cluster.

Cluster profiles are located in the `~/.continuum/adam/profile.d/` directory.

Cluster definition

A cluster definition identifies information about a running cluster, including the cluster name, nodes in the cluster and other platform component options. Cluster definitions are located in the `~/.continuum/adam/cluster.d/` directory.

Air gap installation

Installation in an environment without connectivity to the internet for security reasons.

Getting started

Running the `adam` command shows the options and subcommands that you can use:

```
$ adam
Usage: adam [OPTIONS] COMMAND [ARGS]...

Options:
  --version                Show the version and exit.
  -l, --log-level [info|debug|error]
                           Logging level [default: debug]
  -h, --help                Show this message and exit.

Commands:
  cmd                      Execute a command on the nodes
```

(continues on next page)

(continued from previous page)

describe	Describe an Adam cluster or profile
ec2	EC2 options
enterprise-notebooks	Anaconda Enterprise Notebooks options
info	Display Adam version, system, and license information
list	List Adam clusters and profiles
provision	Provision options
remove	Remove a cluster
repository	Anaconda Repository options
salt	Execute a Salt module
scale	Anaconda Scale options
ssh	SSH to one of the nodes (0-based index)
up	Create a cluster from a profile

To see more information about a subcommand, add the `-h` or `--help` option after the subcommand.

EXAMPLE: `adam up --help`.

For details on using the various subcommands, see [Tasks](#).

For information on installing Adam, creating a cluster, and installing and managing platform components, see the [installation guide](#).

Tasks

Working with cluster profiles

After installing Anaconda Adam and before creating clusters, you must define one or more cluster profiles.

NOTE: An *air gapped machine* needs additional setup and a special cluster profile.

Customizing a cluster profile

Although the default cluster profile described in the [installation guide](#) is appropriate for most environments and use cases, you can customize profile settings as needed.

Cluster profiles are used to define information about a cluster before it is created, including the cluster name, nodes in the cluster, and other platform component options. Cluster files are located in the `~/.continuum/adam/profile.d/` directory.

Cluster definitions are used to identify information about a running cluster, including the cluster name, nodes in the cluster, and other platform component options. Cluster definitions are located in the `~/.continuum/adam/cluster.d/` directory.

- *Sample profile showing all settings*
- *Cluster name*
- *SSH authentication*
- *Node specification*
- *Security settings*

- *Network settings—proxy configuration*
- *Conda settings*
- *Salt settings*
- *System settings*

Sample profile showing all settings

A cluster profile located at `~/.continuum/adam/profile.d/cluster.yaml` with all configurable settings is shown below:

```
name: cluster
provider: bare

bare:
  username: centos
  # password: anaconda # Optional
  port: 22
  keypair: ~/.ssh/my-private-key
  nodes:
    - host: node1.company.com
    - host: node2.company.com
    - host: node3.company.com
    - host: node4.company.com

security:
  flush_iptables: false
  selinux_context: false
  selinux_permissive: false

↪ssl.cf1.rackcdn.com/
server_user: anaconda-server
superuser: superuser
token: qu-a49e2e69-1047-4eab-a879-a2ee9c198381

salt_settings:
  acl:
    - anaconda
  job_pub_port: 14505
  minion_pub_port: 14510
  minion_pull_port: 14511
  minion_ret_port: 14506
  rest_port: 18000
  salt_groupname: anaconda
  salt_password: anaconda
  salt_username: anaconda
  service_scripts: false

```

Cluster name

The name setting specifies the name of the cluster and is used by the `-n` option in Anaconda Adam commands.

EXAMPLE: To create a new cluster named “cluster” from a profile named “profile”:

```
$ adam up -n cluster profile
```

SSH authentication

To connect to remote machines via SSH, Adam requires a valid username, port—default is 22—and an authentication method. Adam supports the following SSH authentication methods:

- Password.
- Key pair—full path to your private key.
- Encrypted key pair—full path to your public key and ssh-agent. The private key must first be added to a running ssh-agent. Use the `agent_pubkey` setting to specify the full path to the associated public key.

For more information about system and account requirements, see [Account access and security](#).

EXAMPLE: To use SSH with a username and password:

```

bare:
  username: centos
  password: anaconda

```

EXAMPLE: To use SSH with a key pair:

```
bare:
  username: centos
  keypair: /full/path/to/key.rsa
```

EXAMPLE: To use SSH with an encrypted key pair:

```
bare:
  username: centos
  agent_pubkey: /full/path/to/key.pub
```

Node specification

The `nodes` setting defines the nodes that exist within the cluster. By default, the first node in the list of nodes is defined as the head node and the remaining nodes are defined as compute nodes.

Each host must be able to connect to the other hosts via the specified FQDN or IP address.

TIP: We recommended using the node's FQDN that matches the hostname on each machine:

EXAMPLE:

```
bare:
  nodes:
    - host: node1.company.com
    - host: node2.company.com
    - host: node3.company.com
    - host: node4.company.com
```

Security settings

The `security` settings let you configure IPTables and SELinux.

To flush iptables, reset `flush_iptables` to `true`. Default value: `false`.

```
security:
  flush_iptables: false
```

To set SELinux to permissive, reset `selinux_permissive` to `true`. Default value: `false`.

```
security:
  selinux_permissive: false
```

To set SELinux contexts, reset `selinux_context` to `true`. Default value: `false`.

```
security:
  selinux_context: false
```

Network settings—proxy configuration

The `network` settings let you install Adam to nodes that access the internet via an HTTP or HTTPS proxy.

To specify an HTTP proxy:

```
network:
  http_proxy: http://server:port/
```

NOTE: Replace `server:port` with the actual server and port.

To specify an HTTPS proxy:

```
network:
  https_proxy: http://server:port/
```

NOTE: Replace `server:port` with the actual server and port.

Conda settings

These are the default settings for configuring conda:

```
conda:
  anaconda_hash: md5=d72add23bc937ccdfc7de4f47deff843
  anaconda_url: http://repo.anaconda.com/archive/Anaconda2-4.4.0-Linux-x86_64.sh
  channel_alias: https://conda.anaconda.org/
  channels:
    - defaults
    - anaconda-adam
  enabled: true
  miniconda_hash: md5=7097150146dd3b83c805223663ebffcc
  miniconda_url: http://repo.anaconda.com/miniconda/Miniconda2-4.3.21-Linux-x86_64.
↪ sh
  rootdir: /opt/continuum
  ssl_verify: False
```

You can set `ssl_verify` to:

- `False`—no SSL verification—default.
- `True`—SSL verification is used and conda verifies certificates for SSL connections.
- `[cert path]`—the string path to a certificate to be used to verify SSL connections.

Salt settings

Salt is the configuration management system used by Adam. The `salt_settings` let you configure the network options, access control list and API user credentials used by Salt.

Use the settings below to specify the ports used by the Salt master, minions and REST API:

```
plugins:
  salt_settings:
    job_pub_port: 14505
    minion_pub_port: 14510
    minion_pull_port: 14511
    minion_ret_port: 14506
    rest_port: 18000
```

Use the `acl` setting to specify an access control list that defines non-root system users who can execute Salt commands:

```
plugins:
  salt_settings:
    acl:
      - anaconda
```

Use the settings below to specify the username, password and group that gets created across the cluster and owns the directory and files located in the root installation directory—default: `/opt/continuum`:

```
plugins:
  salt_settings:
    salt_username: anaconda
    salt_password: anaconda
    salt_groupname: anaconda
```

If you do not want to store a clear text password in the cluster profile or cluster definition file, set `salt_password` to an empty string:

```
plugins:
  salt_settings:
    salt_username: anaconda
    salt_password: ''
    salt_groupname: anaconda
```

In this case, Adam prompts for a password in the CLI and only stores the password in memory for the duration of the command or job.

System settings

The `tmp_dir` setting lets you specify the download directory where temporary installers are downloaded—default: `/tmp`:

```
system:
  tmp_dir: /tmp
```

Viewing cluster profile information

To view a list of cluster profiles, run `adam list profiles`:

```
$ adam list profiles
profile
second-profile
third-profile
```

To view more detailed information about a profile, run:

```
$ adam describe -p [profile-name]
```

You may also use the `--verbose` flag for increased detail.

EXAMPLE: To view verbose information about the profile named “profile”:

```
$ adam describe -p profile --verbose
bare:
  keypair: ~/.ssh/my_keypair.pem
```

(continues on next page)

(continued from previous page)

```

nodes:
- host: 192.168.1.1
- host: 192.168.1.2
- host: 192.168.1.3
- host: 192.168.1.4
port: 22
username: centos
name: cluster
provider: bare
security:
  flush_iptables: false
  selinux_context: false
  selinux_permissive: false

```

Working with clusters

Defining one or more cluster profiles and creating clusters are described in the *installation guide*.

Provisioning a cluster

To provision or reprovision an existing cluster, run:

```
$ adam provision -n [cluster-name]
```

EXAMPLE: To provision the cluster named “cluster”:

```
$ adam provision -n cluster
```

Customizing the provision command—advanced

By default, the `adam provision` command:

- Checks SSH connectivity.
- Creates a default user.
- Installs Salt.
- Syncs formulas.
- Provisions enabled plugins and security settings that are defined in the cluster’s profile.

To run only a portion of this provisioning process, use `adam provision` options and subcommands to control what happens during provisioning.

Run `adam provision --help` to see the available options and subcommands:

```

$ adam provision --help
Usage: adam provision [OPTIONS] COMMAND [ARGS]...

Execute all the provisioning steps for a cluster

See subcommands help for more info. Usage: adam provision -n

```

(continues on next page)

(continued from previous page)

```
Options:
  -n, --cluster TEXT      Cluster name [required]
  --flush-iptables        Flush IPTables [default: False]
  --selinux-permissive    Set SELinux to permissive [default:
                          False]
  --selinux-context       Set SELinux contexts [default: False]
  --plugins               Install enabled plugins on provision
                          [default: False]
  -h, --help              Show this message and exit.

Commands:
  anaconda-user           Create the default anaconda user in all
                          the nodes
  check-ssh               Check SSH connection to the nodes
  flush-iptables          Flush IPTables
  plugins                 Provision enabled plugins
  roles                   Set roles on the cluster nodes
  salt                    Provision Salt
  security-settings       Execute the security settings
  selinux-context         Set SELinux contexts
  selinux-permissive      Set SELinux to permissive
  sync                    Sync formulas and settings
```

EXAMPLE: To check SSH connectivity to all of the nodes in an existing cluster:

```
$ adam provision -n cluster check-ssh
Checking SSH connection to nodes
2016-10-03 22:10:49,327 - adam.models - DEBUG - Checking ssh
connection for 54.88.20.164
2016-10-03 22:10:50,905 - adam.models - DEBUG - SSH
connection to 54.88.20.164: OK
2016-10-03 22:10:51,008 - adam.models - DEBUG - Checking ssh
connection for 52.90.168.130
2016-10-03 22:10:51,996 - adam.models - DEBUG - SSH
connection to 52.90.168.130: OK
+-----+-----+
| Node IP      | SSH Available |
+-----+-----+
| 54.88.20.164 | True          |
| 52.90.168.130 | True          |
+-----+-----+
| All nodes    | True          |
+-----+-----+
```

Viewing cluster information

To view a list of running clusters, run `adam list`:

```
$ adam list
cluster
second-cluster
third-cluster
```

To view detailed information about a cluster, run:

```
$ adam describe -n [cluster-name]
```

EXAMPLE: To view information about the cluster named “cluster”:

```
$ adam describe -n cluster
conda:
  anaconda_hash: md5=7097150146dd3b83c805223663ebffcc
  anaconda_url: https://repo.anaconda.com/miniconda/Miniconda2-4.3.21-Linux-x86_64.sh
↪ #adam-ci
  enabled: true
  rootdir: /opt/continuum
name: cluster
nodes:
- host: ci_head_1
  keypair: ~/.ssh/my_private_key
  port: 22
  username: root
- host: ci_compute_1
  keypair: ~/.ssh/my_private_key
  port: 22
  username: root
```

Adding nodes to an existing cluster

1. In the existing cluster profile, add `host` lines to specify the additional node(s).

EXAMPLE: You have this existing cluster profile, `~/.continuum/adam/profile.d/profile.yaml`:

```
name: profile
provider: bare

bare:
  username: centos
  # password: password # Optional
  port: 22
  keypair: ~/.ssh/my-private-key
  nodes:
  - host: node1.company.com
  - host: node2.company.com
  - host: node3.company.com
  - host: node4.company.com
```

You want to add the following nodes:

- node10.company.com
- node11.company.com
- node12.company.com

Assuming these nodes use the same authentication mode as the existing nodes, add a `host` line for each node:

```
name: profile
provider: bare

bare:
  username: centos
```

(continues on next page)

(continued from previous page)

```
# password: password # Optional
port: 22
keypair: ~/.ssh/my-private-key
nodes:
- host: node1.company.com
- host: node2.company.com
- host: node3.company.com
- host: node4.company.com
- host: node10.company.com
- host: node11.company.com
- host: node12.company.com
```

2. Run the `adam up` command to provision the cluster.

EXAMPLE: To use the profile named “profile” to provision the cluster named “cluster”, run:

```
$ adam up -n cluster profile
```

You are prompted to overwrite the cluster definition file located at `~/.continuum/adam/cluster.d/cluster.yaml` to include the newly defined nodes.

During the provisioning process, Adam will install on the new nodes and will not reinstall on the previously defined nodes.

Managing Anaconda across a cluster

Using Anaconda Scale, you can create and manage conda packages, including Python and R, in multiple conda environments across your nodes.

For more information about installing and managing Anaconda across a cluster, see [Anaconda Scale](#).

Using SSH to connect to nodes

To SSH to the head node in a cluster, run:

```
$ adam ssh -n [cluster-name]
```

EXAMPLE: To SSH to the head node in a cluster named “cluster”:

```
$ adam ssh -n cluster
Last login: Wed Jun 29 03:08:49 2016 from 172.18.0.1
[root@192.168.1.1 ~]#
```

To connect to a specific node, include the node number after the cluster name. Node 0 is the head node, node 1 is the first compute node, and so on.

EXAMPLE: To SSH to the second compute node in a cluster named “cluster”:

```
$ adam ssh -n cluster 2
Last login: Wed Jun 29 03:10:14 2016 from 172.18.0.1
[root@192.168.1.3 ~]#
```

Running remote commands

To execute remote commands on a cluster, run:

```
$ adam cmd -n [cluster-name] -t [target-nodes] [command]
```

EXAMPLE: To run the `date` command on all nodes in a cluster named “cluster”:

```
$ adam cmd -n cluster date
192.168.1.1: Wed Jun 29 03:08:10 UTC 2016
192.168.1.2: Wed Jun 29 03:08:10 UTC 2016
192.168.1.3: Wed Jun 29 03:08:10 UTC 2016
192.168.1.4: Wed Jun 29 03:08:10 UTC 2016
```

Executing Salt modules

To execute Salt modules, run:

```
$ adam salt -n [cluster-name] [nodes] [module-name]
```

EXAMPLE: To execute the “test.ping” Salt module on all nodes in a cluster named “cluster”:

```
$ adam salt -n cluster '*' test.ping
192.168.1.1: true
192.168.1.2: true
192.168.1.3: true
192.168.1.4: true
```

Removing a cluster

To remove the cluster definition file for an existing bare-metal cluster:

1. Run:

```
$ adam remove -n [cluster-name]
```

2. When prompted, type `y`.

EXAMPLE: To remove the cluster named “cluster”:

```
$ adam remove -n cluster
Are you sure you want to remove the cluster cluster? [y/N]: y
```

To remove an EC2 cluster, see the removal instructions at the end of the [cloud installation guide](#).

Working with platform components

- [Overview](#)
- [Viewing a platform component’s status](#)
- [Stopping services for a platform component](#)

- *Restarting services for a platform component*

Overview

Using Anaconda Adam, you can install and manage the Anaconda platform components listed below. An Adam command for managing an Anaconda component has the format:

```
$ adam [platform-component] [command]
```

Platform component	Adam Command Prefix
Anaconda Enterprise Notebooks	adam enterprise-notebooks
Anaconda Repository	adam repository
Anaconda Scale	adam scale

You can also use Adam to install and manage the Anaconda platform on *Amazon EC2 cloud-based nodes* and *air gapped machines*.

Default usernames and passwords

The default administrator usernames and passwords for each platform component are:

Platform component	Username	Password
Anaconda Enterprise Notebooks	wakari	anaconda
Anaconda Repository	superuser	anaconda
Jupyter Notebook	-	anaconda

Platform component documentation

For more information on a platform component, see:

- *Anaconda Enterprise Notebooks*.
- *Anaconda Repository*.
- *Anaconda Scale*.

Viewing a platform component's status

To view the status of a platform component, run:

```
$ adam [platform-component] -n [cluster-name] status
```

EXAMPLE: To view the status of Repository on a cluster named “cluster”:

```
$ adam repository -n cluster status
```

Stopping services for a platform component

To stop services related to a platform component, run:

```
$ adam [platform-component] -n [cluster-name] stop
```

EXAMPLE: To stop Repository services on a cluster named “cluster”:

```
$ adam repository -n cluster stop
```

Restarting services for a platform component

To restart services related to a platform component, run:

```
$ adam [platform-component] -n [cluster-name] restart
```

EXAMPLE: To restart Repository services on a cluster named “cluster”:

```
$ adam repository -n cluster restart
```

Viewing your Adam version and license

To view version and license information, run `adam info`:

```
$ adam info
Adam version: 4.1.0
Plugins:
  adam_enterprise_notebooks: 4.1.0
  adam_repository: 4.1.0
  adam_notebook: 4.1.0
  adam_dask: 4.1.0

Platform: Darwin-15.6.0-x86_64
Darwin Kernel Version 15.6.0: Thu Jun 23 18:25:34 PDT 2016;
root:xnu-3248.60.10~1/RELEASE_X86_64
Python version: 3.5.1 |Continuum Analytics, Inc.| (default,
Dec 7 2015, 11:24:55)
[GCC 4.2.1 (Apple Inc. build 5577)]
Processor: i386
Byte-ordering: little

License information:
Number of nodes currently in use: 14
Number of licensed nodes: 16
Number of managed clusters: 2

Valid platform component licenses:
1: Anaconda Repository Enterprise. End date: 2018-05-24
2: Anaconda Cluster. End date: 2018-05-24
3: Wakari Enterprise. End date: 2018-05-24
4: MKL Optimizations. End date: 2018-05-24
5: IOPro. End date: 2018-05-24
6: Accelerate. End date: 2018-05-24
```

Updating Adam

To update Anaconda Adam to a newer version:

1. Delete the existing Adam installation directory. By default, this is `~/adam`.

NOTE: *Cluster profile* and *cluster definition* files are stored in `~/.continuum/adam`, which is preserved during the update process.

2. *Re-install Adam.*

Troubleshooting

- *Errors when creating or provisioning a cluster*
- *Error: unsupported or unrecognized field*

Errors when creating or provisioning a cluster

You get errors when you run `adam up` to create a cluster or `adam provision` to provision a cluster.

Cause

These errors may be caused by an invalid SSH private key or incorrect settings in a cluster profile.

Solution

Verify the following:

- The contents of your SSH private key are correct and, on Mac/Linux, set to 600 permissions.
- The user name in the cluster profile, such as `username: centos`, is defined correctly.
- The cluster profile settings are defined correctly in `~/.continuum/adam/profile.d/<profile_name>.yaml`.

Error: unsupported or unrecognized field

When running Adam commands, you get an error similar to the following:

```
2016-12-05 11:09:50,120 - adam.config - ERROR - {'notebook':  
'Rogue field'}  
Error: One or more fields is not supported or recognized by  
this version of Anaconda Adam. Correct or remove the  
unsupported field in the cluster YAML profile or cluster  
definition YAML file, and try the operation again. See the  
above errors for more details: {'notebook': 'Rogue field'}
```

Cause

There is an unsupported or unrecognized field in a cluster profile or definition file. If you have updated to a newer version of Adam, some fields in the cluster profile or cluster definition file may have been renamed or removed between versions.

Solution

1. In the cluster profile file in the `~/ .continuum/adam/profile.d` directory or the cluster definition file in the `~/ .continuum/adam/cluster.d` directory, remove or rename the field shown in the error.
2. Retry the command.

FAQs

- *Does Anaconda Adam work with a cluster that already has a managed Spark/Hadoop stack?*
- *Which cloud providers does Adam support?*
- *Can I use Adam with a different cloud provider?*
- *Which network ports need to be accessible from the client machine and cluster nodes?*

Does Anaconda Adam work with a cluster that already has a managed Spark/Hadoop stack?

Yes, you can install Adam alongside existing Hadoop distributions such as Cloudera CDH or Hortonworks HDP. You can use Adam to manage Python and R conda packages and environments across a cluster.

Which cloud providers does Adam support?

Currently, Adam offers full support for Amazon Elastic Compute Cloud (EC2).

Can I use Adam with a different cloud provider?

Yes, you can manually create instances on another cloud provider and then provision the nodes. For more information, see [Tasks](#).

Which network ports need to be accessible from the client machine and cluster nodes?

For communication between the cluster nodes, ports 22, 4505 and 4506 are used to provision the cluster via SSH and Salt.

Help and support

Priority support is included with the purchase of an Anaconda subscription. Visit the [support](#) section of our website for documentation and contact information for support.

Training and consulting

Training and consulting are available for the Anaconda platform and all Anaconda platform components. For more information, contact sales@anaconda.com.

Release notes

Below is a summary of platform component updates, features, bug fixes, and backend improvements for each Anaconda Adam release.

- *Anaconda Adam 4.4.0*
- *Anaconda Adam 4.2.14*
- *Anaconda Adam 4.2.13*
- *Anaconda Adam 4.2.12*
- *Anaconda Adam 4.2.11*
- *Anaconda Adam 4.2.10*
- *Anaconda Adam 4.2.9*
- *Anaconda Adam 4.2.8*
- *Anaconda Adam 4.2.7*
- *Anaconda Adam 4.2.6*
- *Anaconda Adam 4.2.5*
- *Anaconda Adam 4.2.4*
- *Anaconda Adam 4.2.3*
- *Anaconda Adam 4.2.2*
- *Anaconda Adam 4.2.1*
- *Anaconda Adam 4.2.0*
- *Anaconda Adam 4.1.2*
- *Anaconda Adam 4.1.1*
- *Anaconda Adam 4.1.0*
- *Anaconda Adam 4.0.1*
- *Anaconda Adam 4.0.0*
- *Anaconda Adam 1.6.2*
- *Anaconda Adam 1.6.0*
- *Anaconda Adam 1.5.5*
- *Anaconda Adam 1.5.4*
- *Anaconda Adam 1.5.3*
- *Anaconda Adam 1.5.1*
- *Anaconda Adam 1.5.0*

- *Anaconda Adam 1.4.2*
- *Anaconda Adam 1.4.1*
- *Anaconda Adam 1.4.0*

Anaconda Adam 4.4.0

Released: June 20, 2017

Platform Component	Version	Plugin Version
Anaconda/Miniconda	4.4.0/4.3.21	-
Anaconda Enterprise Notebooks	4.1.2	4.2.14
Anaconda Repository	2.30.3	4.4.0
Anaconda Scale (Dask/Distributed)	0.15.0/1.17.1	4.4.0
Anaconda Scale (Jupyter Notebook)	5.0.0	4.2.14

Download Anaconda Adam:

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.4.0/download/adam-installer-4.4.0-Linux-x86_64.sh
- MD5: 64cc02dcaaf7829144cd82db786ab775
- SHA256: 663e2f93177830badadf5dea6647cb0e3d5376770999b85bb02d535d13cfac6d

Platform Component Updates:

- Updated to Anaconda 4.4.0 (conda 4.3.21)
- Updated to Miniconda 4.3.21 (conda 4.3.21)
- Updated to Anaconda Repository 2.30.3
- Updated to Dask 0.15.0 and Distributed 1.17.1

Anaconda Adam 4.2.14

Released: April 28, 2017

Platform Component	Version	Plugin Version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Enterprise Notebooks	4.1.2	4.2.14
Anaconda Repository	2.29.1	4.2.14
Anaconda Scale (Dask/Distributed)	0.14.1/1.16.1	4.2.14
Anaconda Scale (Jupyter Notebook)	5.0.0	4.2.14

Download Anaconda Adam:

- SHA256: 43275084838a698fee7329651d55b20b3087037cc14bec04e27d6d985d402fbd

Platform Component Updates:

- Updated to Anaconda Enterprise Notebooks 4.1.2
- Updated to Anaconda Repository 2.29.1
- Updated to Dask 0.14.1 and Distributed 1.16.1
- Updated to Jupyter Notebook 5.0.0

Anaconda Adam 4.2.13

Released: March 2, 2017

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Enterprise Notebooks	4.1.1	4.2.11
Anaconda Repository	2.27.2	4.2.13
Anaconda Scale (Dask/Distributed)	0.14.0/1.16.0	4.2.13
Anaconda Scale (Jupyter Notebook)	4.3.1	4.2.11

Platform component updates

- Updated to Anaconda Repository 2.27.2.
- Updated to Dask 0.14.0 and Distributed 1.16.0.

Anaconda Adam 4.2.12

Released: February 3, 2017

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Enterprise Notebooks	4.1.1	4.2.11
Anaconda Repository	2.26.3	4.2.11
Anaconda Scale (Dask/Distributed)	0.13.0/1.15.0	4.2.11
Anaconda Scale (Jupyter Notebook)	4.3.1	4.2.11

Bug fixes

Fixed Anaconda/Miniconda download links to be compatible with new `repo.anaconda.com` CDN.

Download Adam

Anaconda Adam 4.2.11

Released: January 16, 2017

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Enterprise Notebooks	4.1.1	4.2.11
Anaconda Repository	2.26.3	4.2.11
Anaconda Scale (Dask/Distributed)	0.13.0/1.15.0	4.2.11
Anaconda Scale (Jupyter Notebook)	4.3.1	4.2.11

Features

Implemented default password in Jupyter Notebooks.

Backend improvements

- Disable automatic updates of conda.
- Updates for compatibility with conda 4.3.x features.

Platform component updates

- Updated to Anaconda Enterprise Notebooks 4.1.1.
- Updated to Anaconda Repository 2.26.3.
- Updated to Dask 0.13.0 and Distributed 1.15.0.
- Updated to Jupyter Notebook 4.3.1.
- Removed Anaconda Accelerate as a standalone platform component (now installed as part of Anaconda Scale).

Download Adam

Anaconda Adam 4.2.10

Released: December 5, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.7
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Repository	2.25.1	4.2.10
Anaconda Scale (Dask/Distributed)	0.12.0/1.14.3	4.2.10
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.7

Platform component updates

- Updated to Anaconda Repository 2.25.1.
- Updated to Dask 0.12.0 and Distributed 1.14.3.
- Removed Anaconda Mosaic.

Download Adam

Anaconda Adam 4.2.9

Released: November 29, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.7
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.7
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.7
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.7

Bug fixes

Fixed scripts that were not included in the release bundle (required for `service_scripts` setting).

Anaconda Adam 4.2.8

Released: November 29, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.7
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.7
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.7
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.7

Bug fixes

Fixed issue with cluster profile settings not being migrated to cluster definition file.

Download Adam

Anaconda Adam 4.2.7

Released: November 16, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.7
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.7
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.7
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.7

Features

Added configuration settings for `salt_username`, `salt_groupname` and `salt_password`, for a user that is created across the cluster and owns the directory and files located in the root installation directory.

Backend improvements

Added retries for Salt minion/API connection.

Download Adam

Anaconda Adam 4.2.6

Released: November 9, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.6
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.3
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Bug fixes

Fixed installation issue with Anaconda Mosaic related to conda environments.

Backend improvements

Reverted to `requests` for file downloads via Salt HTTP module backend.

Anaconda Adam 4.2.5

Released: November 9, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.2.12	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.1
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.3
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Platform component updates

Updated to Miniconda 4.2.12 (conda 4.2.12).

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.5/download/adam-installer-4.2.5-Linux-x86_64.sh.

Anaconda Adam 4.2.4

Released: November 8, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.1.11	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.1.0	4.2.4
Anaconda Mosaic	1.3.1	4.2.1
Anaconda Repository	2.23.1	4.2.4
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.3
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Features

- Added support for creating and updating environments using `conda env` YAML files and listing and removing environments with `adam scale env`.
- Added `tmp_dir` setting to cluster profile to configure temporary download location.
- Added support for removing conda environments using `adam scale conda remove -n my-env --all`.

Backend improvements

- Added support for downloads from CDN by enabling location header redirects when using `curl`.
- Improved handling and catching for errors returned from Salt.

Bug fixes

- Fixed handling of proxy settings (including `.condarc` files) in cluster configuration/profile.
- Fixed handling of security settings in cluster definition when using Amazon EC2 instances.
- Fixed ownership for license directory in Anaconda Scale `rootdir`; default: `/opt/continuum/anaconda/licenses`.

Platform component updates

- Updated to Anaconda Enterprise Notebooks 4.1.0.
- Updated to Anaconda Repository 2.23.1.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.4/download/adam-installer-4.2.4-Linux-x86_64.sh.

Anaconda Adam 4.2.3

Released: October 24, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.1.11	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.0.0	4.2.1
Anaconda Mosaic	1.3.1	4.2.1
Anaconda Repository	2.22.0	4.2.3
Anaconda Scale (Dask/Distributed)	0.11.1/1.13.3	4.2.3
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Backend improvements

- Updated `ssl_verify` setting to handle various inputs (true, false, or string).
- Switched to `curl` for downloading Anaconda/Miniconda in environments with SSL/proxies.

Platform component updates

- Updated to Anaconda Repository 2.22.0.
- Updated to Dask 0.11.1 and Distributed 1.13.3.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.3/download/adam-installer-4.2.3-Linux-x86_64.sh.
- MD5: a484a933afcebb99bafbc5bde4e63081.

Anaconda Adam 4.2.2

Released: October 19, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.1.11	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.0.0	4.2.1
Anaconda Mosaic	1.3.1	4.2.1
Anaconda Repository	2.21.0	4.2.1
Anaconda Scale (Dask/Distributed)	0.11.0/1.12.2	4.2.1
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Bug fixes

Implemented various fixes related to conda configuration file (`.condarc`) and environment variable (`CONDARC`).

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.2/download/adam-installer-4.2.2-Linux-x86_64.sh.

Anaconda Adam 4.2.1

Released: October 14, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.1.11	-
Anaconda Accelerate	2.3.0	4.2.1
Anaconda Enterprise Notebooks	4.0.0	4.2.1
Anaconda Mosaic	1.3.1	4.2.1
Anaconda Repository	2.21.0	4.2.1
Anaconda Scale (Dask/Distributed)	0.11.0/1.12.2	4.2.1
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.1

Features

- Improved output when checking node status (using `Salt test.ping`).
- Added configuration settings to cluster profile related to Salt API username, password, and group.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.1/download/adam-installer-4.2.1-Linux-x86_64.sh.
- MD5: f8b01e94cf6b114b4d9df0f2074206a2.

Anaconda Adam 4.2.0

Released: October 6, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.2.0/4.1.11	-
Anaconda Accelerate	2.3.0	4.2.0
Anaconda Enterprise Notebooks	4.0.0	4.2.0
Anaconda Mosaic	1.3.1	4.2.0
Anaconda Repository	2.21.0	4.2.0
Anaconda Scale (Dask/Distributed)	0.11.0/1.12.2	4.2.0
Anaconda Scale (Jupyter Notebook)	4.2.3	4.2.0

Features

- Improved error messaging for missing/incompatible cluster profile fields.
- Improved handling of state for installed/enabled platform components.
- Simplified `adam describe` output to hide platform components that are not installed.

Backend improvements

- Renamed `salt` to `salt_settings` in cluster profile and added documentation.
- Added conda canary builds to test framework.

Bug fixes

- Fixed user/group ownership for platform component license directories.
- Improved validation of SSH key pairs, passwords, or agent public keys.
- Fixed check for existing Anaconda/Supervisor installations.
- Improved hash check for Miniconda downloads.
- Improved retry functionality for commands executed in parallel across multiple nodes.
- Improved handling of returned states from remote conda commands.
- Print URL when opening/viewing platform components if no browser is available.

Platform component updates

- Updated to Anaconda 4.2.0 (conda 4.2.9).
- Updated to Anaconda Repository 2.21.0.
- Updated to Dask 0.11.0 and Distributed 1.12.2.
- Updated to Jupyter Notebook 4.2.3.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.2.0/download/adam-installer-4.2.0-Linux-x86_64.sh.

- SHA256: 0556ee1b7e8bcd379faf6c2089e7fb525d2845187361a2a96d99a281ba207108.

Anaconda Adam 4.1.2

Released: August 24, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.1.11	-
Anaconda Accelerate	2.3.0	4.1.0
Anaconda Enterprise Notebooks	4.0.0	4.1.1
Anaconda Mosaic	1.3.1	4.1.0
Anaconda Repository	2.19.7	4.1.1
Anaconda Scale (Dask/Distributed)	0.10.2/1.11.3	4.1.0
Anaconda Scale (Jupyter Notebook)	4.2.2	4.1.0

Features

Added support for installations via proxy (HTTP and HTTPS).

Bug fixes

Fixed issue with the creation of a custom home directory for the `anaconda` user.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.1.2/download/adam-installer-4.1.2-Linux-x86_64.sh.

Anaconda Adam 4.1.1

Released: August 18, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.1.11	-
Anaconda Accelerate	2.3.0	4.1.0
Anaconda Enterprise Notebooks	4.0.0	4.1.0
Anaconda Mosaic	1.3.1	4.1.0
Anaconda Repository	2.19.7	4.1.0
Anaconda Scale (Dask/Distributed)	0.10.2/1.11.3	4.1.0
Anaconda Scale (Jupyter Notebook)	4.2.2	4.1.0

Bug fixes

- Fixed issue with Salt API job responses.
- Fixed issue with `invoke_shell` buffer size.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.1.1/download/adam-installer-4.1.1-Linux-x86_64.sh.
- MD5: 48a6fda5c16842ea2f138fe59723f425.

Anaconda Adam 4.1.0

Released: August 17, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.1.11	-
Anaconda Accelerate	2.3.0	4.1.0
Anaconda Enterprise Notebooks	4.0.0	4.1.0
Anaconda Mosaic	1.3.1	4.1.0
Anaconda Repository	2.19.7	4.1.0
Anaconda Scale (Dask/Distributed)	0.10.2/1.11.3	4.1.0
Anaconda Scale (Jupyter Notebook)	4.2.2	4.1.0

Bug fixes

- Fixed issue when attempting to disable SELinux.
- Fixed licensing check when recreating an existing cluster.
- Fixed use of `host` during installation of Anaconda Enterprise Notebooks.

Backend improvements

- Renamed `fqdn` to `host` in cluster profile.
- Changed default AEN Gateway port to 8089 in Anaconda Enterprise Notebooks.
- Changed default system account to `anaconda-server` for Anaconda Repository.
- Added diagnostic SSH checks to initial cluster provision.
- Implemented asynchronous Salt jobs for cluster-wide tasks.
- Added support for DSA and ECDSA SSH keys.
- Added optional `invoke_shell` mode for installations with restricted `sudo` functionality.
- Updated to Salt 2016.3.1.

Platform component updates

- Updated to Miniconda 4.1.11 (conda 4.1.11).
- Updated to Anaconda Repository 2.19.7.
- Updated to Jupyter Notebook 4.2.2.
- Initial release of Anaconda Scale platform component (replaces Anaconda for cluster management).

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.1.0/download/adam-installer-4.1.0-Linux-x86_64.sh.

Anaconda Adam 4.0.1

Released: July 23, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	4.0.0
Anaconda Enterprise Notebooks	4.0.0	4.0.1
Anaconda Mosaic	1.3.1	4.0.0
Anaconda Repository	2.19.2	4.0.0
Dask/Distributed	0.10.1/1.11.2	4.0.0
Jupyter Notebook	4.2.1	4.0.0

Backend improvements

- Store Anaconda Adam API certificates and keys in isolated location.
- Disabled `requiretty` setting in `/etc/sudoers` when installing Anaconda Enterprise Notebooks.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.0.1/download/adam-installer-4.0.1-Linux-x86_64.sh.

Anaconda Adam 4.0.0

Released: July 22, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	4.0.0
Anaconda Enterprise Notebooks	4.0.0	4.0.0
Anaconda Mosaic	1.3.1	4.0.0
Anaconda Repository	2.19.2	4.0.0
Dask/Distributed	0.10.1/1.11.2	4.0.0
Jupyter Notebook	4.2.1	4.0.0

Features

- Sync Anaconda Adam version with Anaconda Platform version.
- Fixed password setting for Jupyter Notebook.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/4.0.0/download/adam-installer-4.0.0-Linux-x86_64.sh.
- MD5: 37662cf0d58955fc46205f2059372cd9.

Anaconda Adam 1.6.2

Released: July 21, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	1.6.0
Anaconda Enterprise Notebooks	4.0.0	1.6.0
Anaconda Mosaic	1.3.1	1.6.2
Anaconda Repository	2.19.2	1.6.0
Dask/Distributed	0.10.1/1.11.2	1.6.1
Jupyter Notebook	4.2.1	1.6.0

Features

Added `conda channel_alias` setting for global Anaconda installation.

Platform component updates

- Updated to Dask 0.10.0 and Distributed 1.11.0.
- Updated to Anaconda Mosaic 1.3.1.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.6.2/download/adam-installer-1.6.2-Linux-x86_64.sh.
- MD5: 859d1b4b759cc0562866ee58a8ceeb35.
- SHA256: 5d378bc7cb681f80f0b80435467d1f889788dd5efc61b5be0f1a07c5993d131e.

Anaconda Adam 1.6.0

Released: July 19, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	1.6.0
Anaconda Enterprise Notebooks	4.0.0	1.6.0
Anaconda Mosaic	1.2.3	1.6.0
Anaconda Repository	2.19.2	1.6.0
Dask/Distributed	0.10.0/1.11.0	1.6.0
Jupyter Notebook	4.2.1	1.6.0

Features

- Improvements to air gapped installation process for Adam core library.
- Added optional `sudo_su` mode for installations with restricted `sudo` functionality.
- A `licenses` directory is now created in the root of the `adam` installation location.

Backend improvements

Improved checks for failed remote commands and `conda` commands.

Bug fixes

Fixed hash key/value check for Anaconda/Miniconda installers.

Download Adam

Anaconda Adam 1.5.5

Released: July 14, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	1.5.2
Anaconda Enterprise Notebooks	4.0.0	1.5.2
Anaconda Mosaic	1.2.3	1.5.2
Anaconda Repository	2.19.2	1.5.4
Dask/Distributed	0.10.0/1.11.0	1.5.1
Jupyter Notebook	4.2.1	1.5.2

Bug fixes

Fixed password-based SSH commands used during provision/installation.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.5.5/download/adam-installer-1.5.5-Linux-x86_64.sh.
- MD5: e28887409326f3539743eda9beeff0b6.
- SHA256: 9e6eb3854ed2bff57aab6573804478ec05f8586e8b4ecd8ee6d0cd5faa44d570.

Anaconda Adam 1.5.4

Released: July 13, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.1/4.0.5	-
Anaconda Accelerate	2.3.0	1.5.2
Anaconda Enterprise Notebooks	4.0.0	1.5.2
Anaconda Mosaic	1.2.3	1.5.2
Anaconda Repository	2.19.2	1.5.4
Dask/Distributed	0.10.0/1.11.0	1.5.1
Jupyter Notebook	4.2.1	1.5.2

Features

- Added `conda channels` setting for global Anaconda installation.
- Support for multiple conda channels in conda commands.
- Added explicit Anaconda and platform component installation steps to `adam provision`, `adam ec2`, and `adam up`.
- Added customizable platform component settings to cluster definition.
- Ability to configure security settings for IPTables and SELinux.
- Improved confirmation/details when destroying Amazon EC2 instances.

Bug fixes

Fixed password-based SSH logins for cluster nodes.

Platform component updates

- Updated to Anaconda 4.1.1 (conda 4.1.6).
- Updated to Anaconda Repository 2.19.2.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.5.4/download/adam-installer-1.5.4-Linux-x86_64.sh.
- MD5: 348928b0816c93a9ccb20a32fa6a6b20.
- SHA256: a3f76295b61b02cda3d2f31c24dfd08fdb4739fb7aff3312753c5ba87ca3eaff.

Anaconda Adam 1.5.3

Released: July 11, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.1.0/4.0.5	-
Anaconda Accelerate	2.3.0	1.5.1
Anaconda Enterprise Notebooks	4.0.0	1.5.1
Anaconda Mosaic	1.2.3	1.5.1
Anaconda Repository	2.19.1	1.5.2
Dask/Distributed	0.10.0/1.11.0	1.5.0
Jupyter Notebook	4.2.1	1.5.1

Features

Changed default admin username and password for Anaconda Repository.

Bug fixes

Added `setuptools` as dependency for Adam.

Platform component updates

Updated to Anaconda 4.1.0 (conda 4.1.4).

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.5.3/download/adam-installer-1.5.3-Linux-x86_64.sh.
- MD5: 4e30813039ec5a7010324a3cf577c621.
- SHA256: 83b03a7704b448bda9eec05b1cf6aa0c7b384cb4c4401a820559e077c2c104d6.

Anaconda Adam 1.5.1

Released: July 8, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.0.0/4.0.5	-
Anaconda Accelerate	2.3.0	1.5.1
Anaconda Enterprise Notebooks	4.0.0	1.5.1
Anaconda Mosaic	1.2.3	1.5.1
Anaconda Repository	2.19.1	1.5.1
Dask/Distributed	0.10.0/1.11.0	1.5.0
Jupyter Notebook	4.2.1	1.5.0

Features

- Changed default AEN Gateway port to 8088 in Anaconda Enterprise Notebooks.
- Added profile settings for Anaconda Repository.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.5.1/download/adam-installer-1.5.1-Linux-x86_64.sh.
- MD5: 8dfe05136a4f022c9611092b1cfc2373.
- SHA256: 89b500affce32c0fb2df78b553d2c96277f0d7852037553710838ed4e82df36f.

Anaconda Adam 1.5.0

Released: July 7, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.0.0/4.0.5	-
Anaconda Accelerate	2.3.0	1.5.1
Anaconda Enterprise Notebooks	4.0.0	1.5.0
Anaconda Mosaic	1.2.3	1.5.1
Anaconda Repository	2.19.1	1.5.0
Dask/Distributed	0.10.0/1.11.0	1.5.0
Jupyter Notebook	4.2.1	1.5.0

Backend improvements

Updated license checks to be compatible with new platform component names.

Platform component updates

- Updated to Anaconda Repository 2.19.1.
- Updated to Anaconda Accelerate 2.3.0.
- Updated to Anaconda Mosaic 1.2.3.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.5.0/download/adam-installer-1.5.0-Linux-x86_64.sh.
- MD5: b162d5425b0d41c96da6b65e45f841e7.

Anaconda Adam 1.4.2

Released: July 6, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.0.0/4.0.5	-
Anaconda Accelerate	2.2.0	1.4.1
Anaconda Enterprise Notebooks	4.0.0	1.4.1
Anaconda Mosaic	1.2.2	1.4.1
Anaconda Repository	2.18.1	1.4.1
Dask/Distributed	0.10.0/1.11.0	1.4.2
Jupyter Notebook	4.2.1	1.4.2

Features

Added `adam describe` command to get detailed information about clusters and profiles.

Bug fixes

Fixed issue with compute node registration in Anaconda Enterprise Notebooks.

Platform component updates

- Updated to Dask 0.10.0 and Distributed 1.11.0.
- Updated to Jupyter 1.4.2.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.4.2/download/adam-installer-1.4.2-Linux-x86_64.sh.
- MD5: c8c906b1623bf109813c588a126d7407.
- SHA256: 0c17e670e13da18dc2d64e09980ce790bc0812754802f6937cc9ecc44efd0da0.

Anaconda Adam 1.4.1

Released: June 28, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.0.0/4.0.5	-
Anaconda Accelerate	2.2.0	1.4.1
Anaconda Enterprise Notebooks	4.0.0	1.4.0
Anaconda Mosaic	1.2.2	1.4.1
Anaconda Repository	2.18.1	1.4.1
Dask/Distributed	0.9.0/1.10.2	1.4.1
Jupyter Notebook	-	1.4.1

Features

Updated license checks in Dask and Notebook platform components.

Bug fixes

Fixed issue with license check.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.4.1/download/adam-installer-1.4.1-Linux-x86_64.sh.
- MD5: 5ec1faec73d8cf53c3fdb6742f86daf5.
- SHA256: 8f61c01029eaff31a1910bf56fbc3b33a0a4a845fcd86ddc12c673706dd1e06e.

Anaconda Adam 1.4.0

Released: June 28, 2016

Platform component	Version	Plugin version
Anaconda/Miniconda	4.0.0/4.0.5	-
Anaconda Accelerate	2.2.0	1.4.1
Anaconda Enterprise Notebooks	4.0.0	1.4.0
Anaconda Mosaic	1.2.2	1.4.1
Anaconda Repository	2.18.1	1.4.1
Dask/Distributed	0.9.0/1.10.2	1.4.0
Jupyter Notebook	-	1.4.1

Features

- Added `adam info` command with license information.
- Added `adam remove` command to remove cluster definition file.
- License files are now uploaded to nodes for each platform component.
- Improved handling of license issues.
- Installers are now automatically built and uploaded.

Backend improvements

Updated Salt to 2016.3.0.

Bug fixes

- Fixed Salt API timeout issue.
- Fixed issue with Salt master and minions starting up.

Download Adam

- Link: https://anaconda.org/anaconda-adam/adam-installer/1.4.0/download/adam-installer-1.4.0-Linux-x86_64.sh.
- MD5: 7d9d2ebfb02e33977fb41d1dcf1240fc.
- SHA256: a2f9c98338d4ba4e224ea815bb338d45ee719cc002af0f5c7d18a8f593a33d54.

4.4.3 Anaconda for Cluster Management

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it.

NOTE: Anaconda for cluster management has been replaced by [Anaconda Scale](#). This documentation is made available for existing installations only.

To use Anaconda with a cluster, please use Anaconda Scale and refer to the [Anaconda Scale](#) documentation.

Anaconda for cluster management provides resource management tools to easily deploy Anaconda across a cluster. It helps you manage multiple conda environments and packages (including Python and R) on bare-metal or cloud-based clusters. Supported platforms include Amazon EC2, bare-metal clusters, or even a collection of virtual machines.

Anaconda for cluster management can be used with distributed computation frameworks such as Spark or Dask and works alongside enterprise Hadoop distributions such as Cloudera CDH or Hortonworks HDP.

Anaconda for cluster management is freely available via Anaconda Cloud for unlicensed, unsupported use with up to 4 cluster nodes. Anaconda Workgroup and Enterprise include licenses for 8 and 16 nodes, respectively. If you would like to use Anaconda for cluster management with additional nodes on a bare-metal, on-premises, or cloud-based cluster, please contact sales@anaconda.com.

Features of Anaconda for cluster management:

- Easily install Python and R packages across multiple cluster nodes
- Manage multiple conda environments across a cluster
- Push local conda environments to all cluster nodes
- Manage both cloud-based and bare-metal clusters
- Remotely SSH and upload/download files to and from cluster nodes

Typical configuration of Anaconda for cluster management:

Table of contents:

Quickstart

This quickstart provides a walkthrough of Anaconda for cluster management using Amazon Web Services (AWS) Elastic Compute Cloud (EC2). The steps covered in this quickstart include defining and launching a cloud-based cluster on Amazon EC2, managing conda packages on the cluster nodes, and installing plugins.

Installation

Install Anaconda for cluster management on your local machine following the instructions on the installation page.

Create a provider

A sample providers file (shown below) is included with a new installation of Anaconda for cluster management and is located within the `~/ .acluster/providers.yaml` file.

```
aws_east:
  cloud_provider: ec2
  keyname: my-private-key
  location: us-east-1
  private_key: ~/.ssh/my-private-key.pem
  secret_id: AKIAXXXXXX
  secret_key: XXXXXXXXXX
```

Edit this file and replace the settings and credentials with your information.

Refer to the [Provider settings](#) page for more details about provider settings, including security groups.

You can list the providers with the command:

```
$ acluster list providers
```

Create a profile

A sample profile is included with a new installation of Anaconda for cluster management and is located in the `~/ .acluster/profiles.d/` directory. The sample profile named `aws_profile_sample` is shown below:

```
name: aws_profile_sample
provider: aws_east
num_nodes: 4
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
node_type: m3.large
user: ubuntu
```

You can use this profile to create a 4-node cluster based on Ubuntu 14.04.

Refer to the [Profile settings](#) page for more details about profile settings.

You can list the profiles with the command:

```
$ acluster list profiles
```

Create the cluster

After the provider and profile files are defined, you can create a cluster using the command:

```
$ acluster create demo_cluster --profile aws_profile_sample
```

This will create your new cluster on Amazon EC2 and provision the cluster nodes, which typically requires between 5 and 10 minutes. You will see updates as the tasks and initialization steps are completed.

Install conda packages

Now that you have a cluster running, you can install conda packages using the `acluster conda` command. The `acluster` command can be prepended to most of the conda commands.

To install numpy, scipy, and pandas on all of the cluster nodes, use the following command:

```
$ acluster conda install numpy scipy pandas
```

Note: Refer to the [Conda management](#) page for a full list of remote conda commands.

Install plugins

Anaconda for cluster management supports multiple plugins such as Apache Spark, Hadoop Distributed File System (HDFS), the Jupyter Notebook, and more. These plugins can be installed on the cluster by using the `acluster install` command.

For example, the following command can be used to install IPython Notebook on the cluster:

```
$ acluster install notebook
```

The notebook will be available on `http://{ HEAD_NODE_IP }:8888`. You can open the respective URLs for many of these applications in your browser using the `acluster open` command:

```
$ acluster open notebook
```

Run the `acluster open` command to view a complete list of supported applications.

Destroy the cluster

When you are finished, the following command can be used to destroy the cluster and terminate all instances in it. It will prompt for confirmation before destroying the cluster.

```
$ acluster destroy demo_cluster
```

Further information

Refer to the [Python with Spark How-tos](#) page for more example use cases for use-cases and example scripts.

Creating a cluster

Requirements

- **Client machine:**
 - Windows, Mac, or Linux, 64-bit
 - Anaconda for cluster management client library installed
- **Cluster Nodes:**
 - One or more 64-bit Linux machines with 8+ GB RAM, 8+ cores (recommended)
 - Access to ports 22, 4505, and 4506 from the client machine to the cluster nodes to provision the cluster via SSH and Salt

Supported operating systems

For the cluster nodes, we support and test Anaconda for cluster management with the following Linux distributions:

- CentOS 6 and CentOS 7
- RHEL 6 and RHEL 7
- Ubuntu 12.04 and Ubuntu 14.04

Cloud-based or bare-metal cluster creation

For more information about configuring and creating a cloud-based or bare-metal cluster, refer to the following documentation:

Cloud-based Cluster Setup

Anaconda for cluster management can launch and bootstrap clusters on a variety of cloud services. We currently support [Amazon EC2](#). Other providers such as Microsoft Azure, Rackspace, Google Cloud Platform, and others are on our roadmap. If you are interested in using a cloud provider that is not listed here, please contact us at sales@anaconda.com.

Cloud configuration involves the use of `profiles` and `providers`. Splitting configurations allows users to easily share and distribute specific cluster configurations (`profiles`), while retaining private authentication credentials (`providers`).

1. Provider Setup

Authentication and cloud definitions are managed in a single provider file on the client machine: `~/.acluster/providers.yaml`. A provider file can contain multiple providers with different settings and credentials.

A sample providers file is included with a new installation of Anaconda for cluster management and is located within the `~/.acluster/providers.yaml` file on the client machine. You can edit the contents of this file to reflect the settings and credentials for your cloud provider.

An example `~/.acluster/providers.yaml` file with a provider named `aws_east` that is configured for Amazon EC2 is shown below:

```
aws_east:
  cloud_provider: ec2
  keyname: my-private-key
  location: us-east-1
  private_key: ~/.ssh/my-private-key.pem
  secret_id: AKIAXXXXXX
  secret_key: XXXXXXXXXXXX
```

Note that you will need access to ports 22, 4505, and 4506 from the client machine to the cluster nodes to provision the cluster via SSH and Salt.

Refer to the [Provider settings](#) page for more details about provider settings, including security groups.

Linux or Mac: You should set the permissions of `providers.yaml` file to 0600.

2. Profile Setup

The settings for each cluster are managed in a profile file.

A sample profile is included with a new installation of Anaconda for cluster management and is located in the `~/.acluster/profiles.d/` directory on the client machine. You can edit the contents of this file to reflect the settings for your cluster.

An example profile located at `~/.acluster/profiles.d/profile_name.yaml` and named `profile_name` that is configured to use the `aws_east` provider is shown below:

```
name: profile_name
provider: aws_east
num_nodes: 4
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
node_type: m3.large
user: ubuntu
```

Anaconda for cluster management supports and is tested with the following Linux-based AMIs on Amazon EC2 (us-east-1 region), which can be set as the `node_id`:

OS	AMI	User
Ubuntu 12.04	ami-08faa660	ubuntu
Ubuntu 14.04	ami-d05e75b8	ubuntu
CentOS 6.6	ami-d89fb7b0	root

For more information on AMIs that are available in other Amazon EC2 regions, refer to the [Amazon EC2 documentation](#) or the [Ubuntu Amazon EC2 AMI Locator](#).

Refer to the [Profile settings](#) page for more details about profile settings.

3. Create Cluster

Use the following command to launch a cluster with the specified profile:

```
$ acluster create demo_cluster --profile profile_name
```

Note: Replace `demo_cluster` with the name of your cluster, and `profile_name` with the name of your profile.

After this command is executed, the cloud-based cluster will be created, and you will see updates as the tasks and initialization steps are completed.

A typical launch takes between 5 and 10 minutes, and has output similar to the following:

```
$ acluster create demo_cluster --profile profile_name
Creating cluster
Number of existing nodes: 0
Number of requested nodes: 4
Licensed nodes: 16
License is valid for the current number of nodes.
INFO: Creating new cluster "demo_cluster" with profile "profile_name"
INFO: Creating 4 instances
INFO: Instances configuration:

```

The cluster is now ready for use.

View the [Troubleshooting FAQ](#) if you encounter errors while creating a cluster.

4. Destroy Cluster

If you want to destroy a cluster, use the following command:

```
$ acluster destroy demo_cluster
```

Note: Replace the name `demo_cluster` above with the actual name of your cluster.

After issuing the above command, you will be prompted to confirm termination of the specified cluster.

Bare-metal Cluster Setup

Anaconda for cluster management can be used to manage pre-existing clusters, such as bare-metal machines, collections of virtual machines (Vagrant, Docker, etc.), or previously instantiated cloud instances. These types of installations are collectively referred to as *bare-metal installations*.

Additional bare-metal cluster requirements:

- **Client machine:**
 - Passwordless SSH access to all cluster nodes
- **Cluster Nodes:**
 - Matching user account/credentials on all nodes with passwordless sudo enabled

Provisioning instructions

1. Provider Setup

A sample providers file is included with a new installation of Anaconda for cluster management and is located within the `~/.acluster/providers.yaml` file on the client machine. You can edit the contents of this file to reflect the settings for your bare metal provider.

An example `~/.acluster/providers.yaml` file with a provider named `bare_metal` is shown below:

```
bare_metal:
  cloud_provider: none
  private_key: ~/.ssh/my-private-key
```

Refer to the [Provider settings](#) page for more details about provider settings.

2. Profile Setup

Create a file on the client machine located at `~/.acluster/profiles.d/profile_name.yaml` that defines the following information:

```
name: profile_name
provider: bare_metal
node_id: bare_metal
node_type: bare_metal
user: ubuntu
num_nodes: 4
machines:
  head:
    - 192.168.1.1
  compute:
    - 192.168.1.2
    - 192.168.1.3
    - 192.168.1.4

# Optional for Anaconda Server
# (note that the ports might be different in your configuration)
anaconda_url: http://[your-anaconda-server-ip]:9000/Miniconda-latest-Linux-x86_64.sh
conda_channels:
  - http://[your-anaconda-server-ip]:8080/conda/anaconda-cluster
  - http://[your-anaconda-server-ip]:8080/conda/anaconda
  - defaults
```

The example profile shown above is named `profile_name` and is configured for a 4-node bare-metal cluster.

Refer to the [Profile settings](#) page for more details about profile settings.

3. Configure Cluster

Use the following command to configure a bare-metal cluster with the specified profile:

```
$ acluster create demo_cluster --profile profile_name
```

Note: Replace `demo_cluster` with the name of your cluster, and `profile_name` with the name of your profile.

After this command is executed, the bare-metal cluster will be configured, and you will see updates as the tasks and initialization steps are completed.

A typical bare-metal cluster configuration takes a few minutes, and has output similar to the following:

```
$ acluster create demo_cluster --profile profile_name
Creating cluster
Number of existing nodes: 0
Number of requested nodes: 4
Licensed nodes: 16
License is valid for the current number of nodes.
INFO: Creating new cluster "demo_cluster" with profile "profile_name"

The cluster is now ready for use.

View the [Troubleshooting FAQ](#) if you encounter errors while creating a cluster.

Configuration

After installing Anaconda for cluster management and running any `acluster` command, the `~/ .acluster` directory is created, along with a sample provider file located in `~/ .acluster/providers.yaml` and a sample

profile file located in `~/ .acluster/profiles.d/`.

An example of an `~/ .acluster` directory with multiple clusters and profiles is shown below:

```
/home/user/.acluster
├── clusters.d
│   ├── cluster1.yaml
│   ├── cluster2.yaml
│   └── cluster3.yaml
├── profiles.d
│   ├── profile1.yaml
│   └── profile2.yaml
└── providers.yaml
```

The `profiles.d` directory contains information about cluster setups, including the number and type of nodes, plugins, and other settings.

The `providers.yaml` file contains information about cloud providers.

The `clusters.d` directory contains information about clusters that are currently running.

For more information about profile and provider settings, refer to the following pages:

Profile settings

The following profile settings can be used to define cluster configurations for cloud-based or bare-metal clusters. Each named profile file should contain information for a single cluster definition.

- *Profile settings*
 - *anaconda_url (optional)*
 - *aws (optional)*
 - *conda_channels (optional)*
 - *default_channels (optional)*
 - *channel_alias (optional)*
 - *name*
 - *node_id*
 - *node_type*
 - *num_nodes*
 - *machines (optional)*
 - *plugins (optional)*
 - *provider*
 - *root_size (optional)*
 - *security (optional)*
 - *user*
- *Sample cloud-based profile file*
- *Sample bare-metal profile file*

Profile settings

anaconda_url (optional)

Set a custom location to download Anaconda/Miniconda from (default: Miniconda with Python 2).

```
anaconda_url: http://localhost/miniconda/Miniconda-latest-Linux-x86_64.sh
```

aws (optional)

Set AWS options for all instances:

- `tags` are optional key/value metadata that are assigned to each instance.
- `termination_protection` prevents your instances from being accidentally terminated (default: `true`).
- `use_private_ip` uses the private IP addresses of the AWS nodes instead of the public IP addresses. This is useful if you are using a custom security group (default: `false`).

```
aws:  
  tags:  
    - billingProject: anaconda-cluster  
    - cluster_version: production  
    - ...  
  termination_protection: true  
  use_private_ip: true
```

conda_channels (optional)

Set custom channels to download conda packages from on the cluster nodes. This setting will overwrite all of the configured conda channels, including the default channels. If you are using this setting, you will need to explicitly include the two default channels, `defaults` and `anaconda-cluster`, followed by your custom channels.

```
conda_channels:  
- defaults  
- anaconda-cluster  
- blaze  
- pypi  
- username  
- https://conda.anaconda.org/username/
```

default_channels (optional)

Set `default_channels` to download the default conda packages from the URL defined. This setting will overwrite the default conda channels: <http://repo.anaconda.com>.

```
default_channels: http://localhost/conda/anaconda
```

channel_alias (optional)

Set `channel_alias` to instruct conda to look for channels in a local repository. This setting will overwrite the default: `http://conda.anaconda.org`.

```
channel_alias: http://localhost/conda/
```

name

Name of the profile.

```
name: profile_name
```

node_id

Image to configure on each node. For bare-metal clusters, a dummy value such as `bare-metal` can be used.

```
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
```

node_type

The type of node to launch. For bare-metal clusters, a dummy value such as `bare-metal` can be used.

```
node_type: m3.large
```

num_nodes

Number of nodes to launch (cloud-based) or manage (bare-metal).

```
num_nodes: 4
```

machines (optional)

IP addresses of head and compute nodes in the cluster. Note that only IP addresses should be used with this setting, not hostnames or FQDNs.

This is used along with the *Bare-metal Cluster Setup* and can refer to bare-metal nodes, cloud-based nodes that were manually launched outside of Anaconda for cluster management, or a collection of virtual machines. If SSH is running on a port other than 22, you can optionally include the SSH port number (e.g., `192.168.1.1:2222`).

```
machines:
  head:
    - 192.168.1.1
  compute:
    - 192.168.1.2
    - 192.168.1.3
    - 192.168.1.4
```

plugins (optional)

Install plugins upon cluster creation or provisioning. Some plugins also have configurable settings. Refer to the *Plugin Settings* documentation for more information.

```
plugins:
- notebook
- dask
```

provider

Name of the provider to use to launch instances for a cloud-based or bare-metal cluster. For more information, refer to the *Provider settings* documentation.

```
provider: aws_east
```

root_size (optional)

Size of the root volume (GB). Currently only used for Amazon EBS volumes.

```
root_size: 200
```

security (optional)

Security settings to enable/disable SELinux or flush iptables rules (default: true).

```
security:
  disable_selinux: true
  flush_iptables: true
```

user

User to SSH to the cluster nodes as. This user must have passwordless sudo access.

```
user: ubuntu
```

Sample cloud-based profile file

Below is a sample cloud-based profile named `profile_name` located in the `~/.acluster/profiles/profile_name.yaml` file that is configured with all required and optional settings.

```
name: profile_name
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
node_type: m3.large
num_nodes: 4
provider: aws_east
root_size: 50
user: ubuntu
```

(continues on next page)

(continued from previous page)

```

anaconda_url: http://localhost/miniconda/Miniconda-latest-Linux-x86_64.sh

aws:
  tags:
    - billingProject: anaconda-cluster

plugins:
  - notebook
  - dask

default_channels: http://localhost/conda/anaconda

channel_alias: http://localhost/conda/

conda_channels:
  - defaults
  - anaconda-cluster
  - blaze
  - pypi
  - username
  - https://conda.anaconda.org/username/

security:
  disable_selinux: true
  flush_iptables: true

```

Sample bare-metal profile file

Below is a sample bare-metal profile named `profile_name` located in the `~/.acluster/profiles/profile_name.yaml` file that is configured with all required and optional settings.

```

name: profile_name
node_id: bare_metal
node_type: bare_metal
num_nodes: 4
provider: bare_metal
user: ubuntu
anaconda_url: http://localhost/miniconda/Miniconda-latest-Linux-x86_64.sh

machines:
  head:
    - 192.168.1.1
  compute:
    - 192.168.1.2
    - 192.168.1.3
    - 192.168.1.4

plugins:
  - notebook
  - dask

default_channels: http://localhost/conda/anaconda

channel_alias: http://localhost/conda/

```

(continues on next page)

(continued from previous page)

```
conda_channels:
- defaults
- anaconda-cluster
- blaze
- pypi
- username
- https://conda.anaconda.org/username/

security:
  disable_selinux: false
  flush_iptables: false
```

Provider settings

The following provider settings can be used to define settings for creating cloud-based or bare-metal clusters. The `providers.yaml` file can contain credentials and settings for multiple providers.

- *Provider settings*
 - *cloud_provider*
 - *keyname (optional)*
 - *location (optional)*
 - *private_key*
 - *secret_id (optional)*
 - *secret_key (optional)*
 - *security_group (optional)*
- *Sample providers file*

Provider settings

cloud_provider

Name of the cloud provider (`ec2`, `none`). Use `none` for bare-metal clusters.

```
cloud_provider: ec2
```

keyname (optional)

Name of the key to authenticate with the cluster nodes. This setting is used with a cloud provider.

```
keyname: my-private-key
```

location (optional)

Region or location to use with a cloud provider.

```
location: us-east-1
```

private_key

Path to the private SSH key on the client machine.

```
private_key: ~/.ssh/my-private-key.pem
```

secret_id (optional)

Secret ID to authenticate with a cloud provider.

```
secret_id: AKIA*****
```

secret_key (optional)

Secret key to authenticate with a cloud provider.

```
secret_key: RXE*****
```

security_group (optional)

Security Group to use with a cloud provider. Note that this is the “Group Name” in the AWS Console, not the “Name” or “Group ID”. Note that you will need access to ports 22, 4505, and 4506 from the client machine to the cluster nodes to provision the cluster via SSH and Salt. If this parameter is not specified, then a default Security Group will be created for you, called `anaconda-cluster-default`, with all ports open.

```
security_group: my-security-group
```

Sample providers file

Below is a sample providers file located in the `~/.acluster/providers.yaml` file that is configured with all required and optional settings. The `providers.yaml` file can contain credentials and settings for multiple providers. The sample providers file shown below defines two providers named `aws_east` and `bare_metal` for cloud-based and bare-metal clusters, respectively.

```
aws_east:
  cloud_provider: ec2
  keyname: my-private-key
  location: us-east-1
  private_key: ~/.ssh/my-private-key.pem
  secret_id: AKIAXXXXXX
  secret_key: XXXXXXXXXX
  security_group: my-security-group
```

(continues on next page)

(continued from previous page)

```
bare_metal:  
  cloud_provider: none  
  private_key: ~/.ssh/my-private-key
```

Plugins

- *List of available plugins*
- *Installing Plugins*
- *Plugin Settings*
 - *Conda*
 - *Dask*
 - *HDFS*
 - *Jupyter Notebook*
 - *Custom download settings for plugins*
- *Managing Plugins*
 - *Plugin Status*
 - *Open Plugin UIs*
 - *Restart Plugins*
 - *Stop Plugins*
- *Plugin Notes and Network Ports*
 - *HDFS*
 - *Jupyter Notebook*
 - *Miniconda*
 - *Salt*
 - *Spark*
 - *YARN*

List of available plugins

Anaconda for cluster management can install and manage the following plugins on a cluster:

- Anaconda distribution
- Dask/Distributed
- Ganglia
- IPython Parallel
- Jupyter Notebook

- Salt

The following plugins are unsupported and should only be used for prototyping/experimental purposes:

- Elasticsearch
- HDFS
- Hive
- Impala
- Kibana
- Logstash
- Spark (standalone mode or YARN)
- Storm
- YARN
- ZooKeeper

If you're interested in using Anaconda with production Hadoop clusters, Anaconda for cluster management works with enterprise Hadoop distributions such as [Cloudera CDH](#) or [Hortonworks HDP](#).

On clusters with existing enterprise Hadoop installations, Anaconda for cluster management can manage packages (e.g., for PySpark, SparkR, or Dask) and can install and manage the Jupyter Notebook and Dask plugins.

Installing Plugins

Plugins can be installed using two methods:

1. Using the `cluster_profile.yaml` file when creating or provisioning a cluster.
2. Using the `acluster install` command after the cluster is created.

1. Install plugins with the `profile.yaml` file

When creating or provisioning a cluster, create or edit the file `~/.acluster/profiles.d/profile_name.yaml` as shown in the example below:

```
name: profile_name
provider: aws
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
user: ubuntu
node_type: m3.large
num_nodes: 5
plugins:
  - notebook
  - dask
```

Optionally, you can configure some plugin settings from within your profile. For example, you can specify a password to protect a Jupyter Notebook using:

```
name: profile_name
provider: aws
node_id: ami-d05e75b8 # Ubuntu 14.04, us-east-1 region
user: ubuntu
node_type: m3.large
num_nodes: 5
```

(continues on next page)

(continued from previous page)

```
plugins:
- notebook:
  password: secret
```

Refer to the [Plugin Settings](#) section for more details on configuring plugin settings.

2. Install plugins using the `acluster install` command

After the cluster has been created, you can view a list of available plugins with the command `acluster install` as shown in the example below:

```
$ acluster install
Usage: acluster install [OPTIONS] COMMAND [ARGS]...

  Install plugins across the cluster

Options:
  -h, --help  Show this message and exit.

Commands:
  conda          Install (mini)conda
  dask           Install Dask/Distributed
  elasticsearch  Install Elasticsearch
  ganglia        Install Ganglia
  hdfs           Install HDFS
  hive           Install Hive
  impala         Install Impala
  ipython-parallel Install IPython Parallel
  kibana         Install Kibana
  notebook       Install Jupyter Notebook
  logstash       Install Logstash
  salt           Install Salt
  spark-standalone Install Spark (standalone)
  spark-yarn     Install Spark (YARN)
  storm          Install Storm
  yarn           Install YARN
  zookeeper      Install Zookeeper
```

All of the above subcommands can optionally receive a `--cluster/-x` option to specify a cluster. This option is not required if you only have one cluster running.

Note: Salt is the base for all plugins except Conda. Therefore, the Salt plugin needs to be installed before the other plugins can be installed. Salt is installed by default when you create or provision a cluster using the `acluster create` or `acluster provision` command.

Plugin Settings

The following plugins support custom settings that can be defined within a profile.

Conda

Configure conda packages and environments to be installed upon cluster creation or provisioning:

```
name: profile_name
plugins:
  - conda:
      environments:
        root:
          - numpy
        py27:
          - python=2.7
          - scipy
          - numba
        py34:
          - python=3.4
          - pandas
          - nltk
```

Configure the installation location of conda (default: `/opt/anaconda`):

```
name: profile_name
plugins:
  - conda:
      install_prefix: /opt/another_anaconda
```

Set `conda_sh` to `false` to disable the creation of `/etc/profile.d/conda.sh` on cluster nodes (default: `true`):

```
name: profile_name
plugins:
  - conda:
      conda_sh: false
```

Set `conda_group_name` to any valid unix group (default: `anaconda`):

```
name: profile_name
plugins:
  - conda:
      conda_group_name: anaconda
```

Set `conda_acl` to a list of users who will be given access for Anaconda Cluster admin capabilities. Note: When using this setting at least one user must have `sudo` access during the provisioning phase. Typically, this will include the user previously set above as `user`.

```
name: profile_name
plugins:
  - conda:
      conda_acl:
        - user1
        - user2
```

Set `ssl_verify` to a custom SSL path or to `False` to disable SSL verification for conda. Refer to the [conda documentation](#) for more information.

```
name: profile_name
plugins:
  - conda:
      ssl_verify: False
```

Dask

You can optionally set the number of processes (`nprocs`) to use for the Dask/Distributed workers and the `host` to access the Dask/Distributed UI via a browser. Refer to the [Dask distributed scheduler documentation](#) for more information about these settings.

```
name: profile_name
plugins:
  - dask:
      nprocs: 8
      host: dask-ui.com
```

HDFS

By default, the HDFS plugin is configured to use the following directories: `/data/dfs/nn` on the namenode and `/data/dfs/dn` on the datanodes. When multiple drives are available, the same directories are used on all non-root drives.

You can optionally set custom directories for the HDFS namenode and datanode. For example, the following settings can be used if you want to utilize a large root volume (e.g., using the `root_volume` profile setting with Amazon EC2):

```
name: profile_name
plugins:
  - hdfs:
      namenode_dirs:
        - /data/dfs/nn
      datanode_dirs:
        - /data/dfs/dn
```

Jupyter Notebook

Set a custom password to protect a Jupyter Notebook (default: `acluster`):

```
name: profile_name
plugins:
  - notebook:
      password: acluster
```

Set a custom port for the Jupyter Notebook server (default: `8888`):

```
name: profile_name
plugins:
  - notebook:
      port: 8888
```

Set a custom directory for Jupyter Notebooks (default: `/opt/notebooks`):

```
name: profile_name
plugins:
  - notebook:
      directory: /opt/notebooks
```

Custom download settings for plugins

Most plugins are installed from the standard package management repositories for your Linux distribution. Some plugins are downloaded directly from their source/project website. You can override the default download settings for the following plugins:

```
name: profile_name
plugins:
  - elasticsearch:
      download_url: https://download.elasticsearch.org/elasticsearch/release/org/
↳ elasticsearch/distribution/tar/elasticsearch/2.1.0/elasticsearch-2.1.0.tar.gz
      download_hash: sha1=b6d681b878e3a906fff8c067b3cfe855240bffb
      version: elasticsearch-2.1.0
  - logstash:
      download_url: https://download.elastic.co/logstash/logstash/logstash-2.1.1.tar.
↳ gz
      download_hash: sha1=d71a6e015509030ab6012adcf79291994ece0b39
      version: logstash-2.1.1
  - kibana:
      download_url: https://download.elastic.co/kibana/kibana/kibana-4.3.0-linux-x64.
↳ tar.gz
      download_hash: sha1=d64e1fc0ddeaaab85e168177de6c78ed82bb3a3b
      version: kibana-4.3.0-linux-x64
  - storm:
      source_url: http://apache.arvixe.com/storm/apache-storm-0.9.5/apache-storm-0.9.
↳ 5.tar.gz
      version_name: apache-storm-0.9.5
```

Managing Plugins

The following commands can be used to manage your plugins:

Plugin Status

Check the status of the plugins by using the `acluster status` command:

```
$ acluster status
Usage: acluster status [OPTIONS] COMMAND [ARGS]...

Options:
  -x, --cluster TEXT           Cluster name
  -l, --log-level [info|debug|error]
                                Library logging level
  -h, --help                   Show this message and exit.

Commands:
  conda           Check Conda status
  dask            Check Dask/Distributed status
  elasticsearch   Check Elasticsearch status
  ganglia         Check Ganglia status
  hdfs           Check HDFS status
  hive           Check Hive status
  impala         Check Impala status
  ipython-parallel Check IPython Parallel status
```

(continues on next page)

(continued from previous page)

kibana	Check Kibana status
notebook	Check IPython/Jupyter Notebook status
salt	Check Salt package status
salt-conda	Check Salt Conda module status
salt-key	Check salt-minion keys status
spark-standalone	Check Spark (standalone) status
ssh	Check SSH status
storm	Check Storm status
yarn	Check YARN status

Example:

```
$ acluster status conda
Checking status of conda on cluster: demo_cluster
54.81.187.22: True
54.91.219.252: True
54.163.26.229: True
54.145.10.211: True
Status all: True

$ acluster status salt
54.167.128.130: True
54.205.160.114: True
50.16.32.99: True
50.16.34.82: True
54.163.143.34: True
Status all: True

$ acluster status salt-key
ip-10-156-23-215.ec2.internal: True
ip-10-147-47-235.ec2.internal: True
ip-10-225-181-251.ec2.internal: True
ip-10-237-145-2.ec2.internal: True
ip-10-156-30-32.ec2.internal: True
Status all: True

$ acluster status salt-conda
ip-10-156-23-215.ec2.internal: True
ip-10-237-145-2.ec2.internal: True
ip-10-225-181-251.ec2.internal: True
ip-10-147-47-235.ec2.internal: True
ip-10-156-30-32.ec2.internal: True
Status all: True
```

The multiple salt status checks perform different checks. The `acluster status salt` command verifies that the salt package is installed, the `acluster status salt-key` command verifies that the salt minions are connected to the head node, and the `acluster status salt-conda` command verifies that the salt conda module is distributed across the cluster and is operational.

All of the above checks should return a successful status after executing `acluster install salt`.

Open Plugin UIs

Some of the plugins provide a browser UI that can be displayed to the user. The `acluster open` command is a utility command that opens a browser window corresponding to each plugin. The command:

```
$ acluster open notebook
```

will open a browser window to the Jupyter Notebook (port 8888).

Use the `--no-browser` option to print the URL for the plugin interface without opening a browser window.

```
$ acluster open notebook --no-browser
notebook: http://54.172.82.53:8888
```

Restart Plugins

If a plugin is not working correctly, restart the processes by using the `acluster restart` command.

Stop Plugins

To stop a plugin, use the `acluster stop` command.

Plugin Notes and Network Ports

HDFS

Requires: `salt`

Distributed file system used by many of the distributed analytics engines such as Impala, Hive, and Spark.

Service	Location	Port
NameNode UI	Head node	50070
HDFS Master	Head node	9000
WebHDFS	Head node	14000

Jupyter Notebook

Requires: `salt`

Web-based interactive computational environment for Python.

Service	Location	Port
Notebook	Head node	8888

Notebooks are saved in the directory `/opt/notebooks`. You can upload and download notebooks from the cluster by using the `put` and `get` commands, respectively.

```
$ acluster put mynotebook.ipynb /opt/notebooks/mynotebook.ipynb
$ acluster get /opt/notebooks/mynotebook.ipynb mynotebook.ipynb
```

Miniconda

Python distribution from [Anaconda](#) – ships with Python libraries for large-scale data processing, predictive analytics, and scientific computing.

Salt

Requires: `conda`

Configuration management system.

Service	Location	Port
Salt Master/Minion	All nodes	4505
Salt Master/Minion	All nodes	4506

Spark

Computing framework and analytics engine written in Java/Scala with a Python interface (PySpark).

Service	Location	Port
Spark UI (standalone)	Head node	8080

YARN

Resource manager in which all Hadoop and Hadoop-like jobs are run.

Service	Location	Port
Resource UI	Head node	9026
NodeManager	Compute node(s)	9035

Cluster management

- *Overview*
- *SSH access*
- *Executing commands*
- *Upload/download files*
- *Command history*
- *Centralized logging*
- *Anaconda for cluster management client information*
- *Advanced: Running Salt modules*
- *Advanced: Syncing Salt formulas*

Overview

Anaconda for cluster management provides functionality to easily interact with clusters, including:

- Secure shell (SSH) to cluster nodes

- Executing commands on cluster nodes
- Uploading (put) and downloading (get) files from cluster nodes
- Executing salt module commands: <http://docs.saltstack.com/en/latest/ref/modules/all/>

For a concise overview of all of the available commands, view the Anaconda for cluster management Cheat Sheet.

For the `acluster` commands shown below, you can optionally specify a `--cluster/-x` option to specify a target cluster to operate on. This option is not required if only one cluster is running.

SSH access

The command `acluster ssh` can be used to SSH into any node within the cluster.

The first (optional) argument is a zero-indexed number that refers to a node, where 0 is the head node, 1 is the first compute node, and so on.

Note: This functionality requires SSH. **Windows users:** Install an SSH client such as [PuTTY](#).

Executing commands

The `acluster cmd` command allows commands to be executed across multiple nodes on the cluster. This functionality is performed via salt (default) or fabric (using the `--ssh/-s` flag).

Salt provides faster execution times (especially in large clusters) of remote commands, assuming salt is installed and running on the cluster. Salt is installed by default on cloud providers and can be installed on bare-metal clusters using the command `acluster install salt`.

Fabric provides remote command execution based on SSH, which can be slow in big clusters but does not require salt to be installed on the cluster. Using fabric, you can also target specific nodes using the `--target/-t` option. The `--target/-t` option can receive the keywords 'head' and 'compute', a number (zero-indexed, where 0 is the head node and 1 is the first compute node), or two numbers separated by a comma to target a group of consecutive nodes.

Example:

```
$ acluster cmd 'date'
Executing command "date" target: "*" cluster: "demo_cluster"
4 nodes response: Thu May 14 19:21:48 UTC 2015
1 nodes response: Thu May 14 19:21:44 UTC 2015
1 nodes response: Thu May 14 19:21:47 UTC 2015

$ acluster cmd 'date' --ssh
54.196.149.0: Thu May 14 19:22:06 UTC 2015
54.159.15.86: Thu May 14 19:22:03 UTC 2015
107.21.159.226: Thu May 14 19:22:06 UTC 2015
107.20.60.246: Thu May 14 19:22:06 UTC 2015
54.237.177.104: Thu May 14 19:22:06 UTC 2015
54.227.91.24: Thu May 14 19:22:06 UTC 2015

$ acluster cmd 'date' --ssh -t head
107.21.159.226: Thu May 14 19:23:02 UTC 2015

$ acluster cmd 'date' --ssh -t 3,6
54.196.149.0: Thu May 14 19:23:29 UTC 2015
54.159.15.86: Thu May 14 19:23:26 UTC 2015
54.227.91.24: Thu May 14 19:23:29 UTC 2015
```

Upload/download files

The commands `acluster put` and `acluster get` allow files to be uploaded to and downloaded from any node in the cluster. By default, the `put` and `get` commands target the head node.

Both of the `put` and `get` commands have the same `--target/-t` option, which has the same functionality as `cmd` with the `-ssh/-s` flag.

Example:

```
$ acluster put environment.yml /tmp/env.yml
Uploading file "environment.yml" to "/tmp/env.yml" - cluster: "demo_cluster" - hosts:
"['107.21.159.226']"

$ acluster put environment.yml /tmp/env.yml --all
Uploading file "environment.yml" to "/tmp/env.yml" - cluster: "demo_cluster" - hosts:
"['107.21.159.226', '107.20.60.246', '54.237.177.104', '54.159.15.86', '54.196.149.0',
'54.227.91.24']"

$ acluster put environment.yml /tmp/env.yml -t ,3
Uploading file "environment.yml" to "/tmp/env.yml" - cluster: "demo_cluster" - hosts:
"['107.21.159.226', '107.20.60.246', '54.237.177.104']"

$ acluster put environment.yml /tmp/env.yml -t compute
Uploading file "environment.yml" to "/tmp/env.yml" - cluster: "demo_cluster" - hosts:
"['107.20.60.246', '54.237.177.104', '54.159.15.86', '54.196.149.0', '54.227.91.24']"
```

The `get` command has similar behavior. Although the `-target/-t` option is also available, it might not make sense to download the same file repeatedly since it will get overwritten.

Example:

```
$ acluster get /tmp/env.yml env2.yml
Downloading file "/tmp/env.yml" to "env2.yml" - cluster: "demo_cluster" - hosts:
"['107.21.159.226']"

$ acluster get /tmp/env.yml env2.yml --all
Downloading file "/tmp/env.yml" to "env2.yml" - cluster: "demo_cluster" - hosts:
"['107.21.159.226', '107.20.60.246', '54.237.177.104', '54.159.15.86', '54.196.149.0',
'54.227.91.24']"
Warning: Local file /tmp/env2.yml already exists and is being overwritten.
Warning: Local file /tmp/env2.yml already exists and is being overwritten.
```

Command history

The `acluster history` command displays commands that were previously executed using `acluster`. By default, the ten most recent commands are shown.

```
$ acluster history
2015-06-09 23:39:22,515: acluster create demo_cluster --profile profile_name
2015-06-10 00:00:46,151: acluster ssh
2015-06-10 00:01:35,304: acluster acluster conda install numpy scipy
2015-06-10 00:02:01,029: acluster open notebook
```

Centralized logging

You can install the Elasticsearch, Logstash, and Kibana (ELK) plugins and use them to collect, search, and analyze data. When you install the ELK plugins, they come preconfigured for centralized logging of other Anaconda for cluster management plugins. For more information about plugins, refer to the [Plugins](#) documentation.

To install the ELK plugins, insert the following in your cluster profile before you create or provision a cluster:

```
plugins:
  - elasticsearch
  - logstash
  - kibana
```

or, use the following command to install the ELK plugins on an active cluster:

```
$ acluster install elasticsearch logstash kibana
```

After the ELK plugins are installed, they will begin collecting logs for various services, and the log data can be searched using Elasticsearch and visualized using Kibana. You can open the Kibana UI in your browser using the following command:

```
$ acluster open kibana
```

By default, the following index patterns are available in Kibana:

```
YYYY-MM-DD
salt
hdfs
yarn
spark_yarn
spark_standalone
zookeeper
impala
hive
hbase
hadoop-httpfs
mapreduce
syslog
```

Note that you can use the ELK plugins in a number of different workflows once they are installed on the cluster, including:

- Viewing and searching logs for all cluster-related plugins
- Viewing logs for Spark or YARN jobs for centralized job monitoring and troubleshooting
- Utilizing centralized logging capabilities from your application

Anaconda for cluster management client information

The `acluster info` command displays version information related to the Anaconda for cluster management client installation.

```
$ acluster info
anaconda-cluster version: 1.0
Platform: Darwin-14.3.0-x86_64
Processor: i386
```

(continues on next page)

(continued from previous page)

```
Byte-ordering: little
Python version: 2.7.10 |Continuum Analytics, Inc.| (default, May 28 2015, 17:04:42)
[GCC 4.2.1 (Apple Inc. build 5577)]
apache-libcloud version: 0.16.0
yaml version: 3.11
```

Advanced: Running Salt modules

By default, salt provides quite a bit of functionality in its default modules. All of this functionality is available by using the `acluster function` command.

For example, you can ping all of the cluster nodes to see that they are available:

```
$ acluster function test.ping
ip-10-153-156-45.ec2.internal:
  True
ip-10-169-57-125.ec2.internal:
  True
ip-10-181-18-153.ec2.internal:
  True
ip-10-144-199-24.ec2.internal:
  True
ip-10-113-145-230.ec2.internal:
  True
ip-10-136-78-206.ec2.internal:
  True
```

Advanced functions are also available, such as listing all of the IP address associated with a node:

```
$ acluster function network.ipaddr
ip-10-169-57-125.ec2.internal:
  - 10.169.57.125
ip-10-144-199-24.ec2.internal:
  - 10.144.199.24
ip-10-181-18-153.ec2.internal:
  - 10.181.18.153
ip-10-153-156-45.ec2.internal:
  - 10.153.156.45
ip-10-136-78-206.ec2.internal:
  - 10.136.78.206
ip-10-113-145-230.ec2.internal:
  - 10.113.145.230
```

Another common salt command can be used to install packages using the system package manager:

```
$ acluster function pkg.install httpd
ip-10-136-78-206.ec2.internal:
  ...
  httpd:
    -----
    new:
      2.2.15-39.el6.centos
    old:
  ...
```

(continues on next page)

(continued from previous page)

```
ip-10-144-199-24.ec2.internal:
...
  httpd:
    -----
    new:
      2.2.15-39.el6.centos
    old:
    ...
...

```

For more information on salt commands, see <http://docs.saltstack.com/en/latest/ref/modules/all/>

Advanced: Syncing Salt formulas

The `acluster sync` command is an advanced feature that synchronizes the Salt formulas from the client to the head node and then across the cluster.

Conda management

- *Overview*
- *Installing packages from channels*
- *List of remote conda commands*
- *Example remote conda commands*
 - *Install conda packages*
 - *List conda packages*
 - *Update conda packages*
 - *Remove conda packages*
 - *Create conda environments*
 - *Push conda environments*
 - *List conda environments*

Overview

One of the primary features of Anaconda for cluster management is the remote deployment and management of Anaconda environments across a cluster.

Prepending `acluster` to core `conda` commands will execute those commands across all of the cluster nodes.

For example, to view the conda environments on all of the cluster nodes:

```
$ acluster conda info -e
All nodes (x3) response:
# conda environments:
```

(continues on next page)

(continued from previous page)

```
#
root          *   /opt/anaconda
```

To install numpy on all of the cluster nodes:

```
$ acluster conda install numpy
Installing (u'numpy',) on cluster "demo_cluster"
Node "ip-10-234-8-208.ec2.internal":
    Successful actions: 1/1
Node "ip-10-170-59-28.ec2.internal":
    Successful actions: 1/1
Node "ip-10-232-42-58.ec2.internal":
    Successful actions: 1/1
```

For a concise overview of all of the available commands, view the [Anaconda for cluster management Cheat Sheet](#).

Installing packages from channels

You can install packages from [Anaconda Cloud](#) or from an Anaconda Repository installation by adding the `--channel/-c` option. For example, to install the `apache-libcloud` package from the `anaconda-cluster` channel:

```
$ acluster conda install -c https://conda.anaconda.org/anaconda-cluster apache-
↳ libcloud
Installing (u'apache-libcloud',) on cluster "demo_cluster"
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1
$ acluster conda list | grep apache-libcloud
- 'apache-libcloud: 0.16.0 (py27_0)'
```

List of remote conda commands

The following conda commands are available in Anaconda for cluster management:

- `acluster conda install` – Install package(s)
- `acluster conda update` – Update package(s)
- `acluster conda remove` – Remove package(s)
- `acluster conda list` – List package(s)
- `acluster conda create` – Create conda environment
- `acluster conda info` – Display information about current conda install
- `acluster conda push` – Push conda environment to cluster

For more information about conda, refer to the [conda documentation](#).

Example remote conda commands

Install conda packages

Any conda package can be installed on a cluster managed by Anaconda for cluster management:

```
$ acluster conda install numpy

Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1
```

Verify that the package was installed using the `list` command:

```
$ acluster conda list

All nodes (x2) response:
...
- 'numpy: 1.9.2 (py27_0)'
...
```

You may also install multiple conda packages with a single command:

```
$ acluster conda install scipy pandas scikit-learn
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 3/3
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 3/3

$ acluster conda list
All nodes (x2) response:
...
- 'pandas: 0.16.1 (np19py27_0)'
...
- 'scikit-learn: 0.16.1 (np19py27_0)'
- 'scipy: 0.15.1 (np19py27_0)'
...
```

Note: It is recommended that you install all of the packages you want at once. Installing one package at a time can result in dependency conflicts.

List conda packages

A useful conda command to run on a cluster is to list the packages that are available on the nodes (by default all of the nodes should have the same packages):

```
$ acluster conda list

All nodes (x2) response:
- 'libsodium: 0.4.5 (0)'
- 'sqlite: 3.8.4.1 (1)'
- 'conda-env: 2.1.4 (py27_0)'
- 'python: 2.7.9 (3)'
...
```

Update conda packages

You can also specify which versions of conda packages to install or update:

```
$ acluster conda install pandas==0.13
Installing (u'pandas==0.13',) on cluster "demo_cluster"
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1
$ acluster conda list | grep pandas
- 'pandas: 0.13.0 (np18py27_0)'

$ acluster conda update pandas
Updating (u'pandas',) on cluster "demo_cluster"
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1
$ acluster conda list | grep pandas
- 'pandas: 0.16.1 (np19py27_0)'
```

Remove conda packages

You can remove conda packages across a cluster:

```
$ acluster conda remove pandas
Removing (u'pandas',) on cluster "demo_cluster"
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1

$ acluster conda list | grep pandas
... NO OUTPUT ...
```

Create conda environments

You can also manage conda environments across a cluster with Anaconda for cluster management.

To create a new conda environment that contains Python and numpy, use the command `conda create -n test_env numpy`.

On a cluster, use the same command and simply prepend `acluster` as shown:

```
$ acluster conda create -n test_env numpy
All nodes (x2) response:
Conda environment "test_env" created
```

Once the environment is created, refer to that named environment by adding the `-n` name option to conda commands:

```
$ acluster conda list -n test_env
All nodes (x2) response:
- 'sqlite: 3.8.4.1 (1)'
```

(continues on next page)

(continued from previous page)

```

- 'python: 2.7.9 (3)'
- 'zlib: 1.2.8 (0)'
- 'openssl: 1.0.1k (1)'
- 'system: 5.8 (2)'
- 'tk: 8.5.18 (0)'
- 'setuptools: 15.2 (py27_0)'
- 'pip: 6.1.1 (py27_0)'
- 'readline: 6.2 (2)'
- 'numpy: 1.9.2 (py27_0)'

$ acluster conda install -n test_env requests
Installing (u'requests',) on cluster "d" - target: "*"
Node "ip-10-136-80-92.ec2.internal":
    Successful actions: 1/1
Node "ip-10-63-173-62.ec2.internal":
    Successful actions: 1/1

$ acluster conda list -n test_env
All nodes (x2) response:
- 'sqlite: 3.8.4.1 (1)'
- 'python: 2.7.9 (3)'
- 'zlib: 1.2.8 (0)'
- 'openssl: 1.0.1k (1)'
- 'system: 5.8 (2)'
- 'tk: 8.5.18 (0)'
- 'setuptools: 15.2 (py27_0)'
- 'pip: 6.1.1 (py27_0)'
- 'readline: 6.2 (2)'
- 'numpy: 1.9.2 (py27_0)'
- 'requests: 2.7.0 (py27_0)'

```

Push conda environments

You can also push conda environments from the client machine to the cluster by using a `conda environment.yml` file:

```

$ acluster conda push ./environment.yml
['ip-10-234-8-208.ec2.internal'] nodes response:
Conda environment with "/tmp/anaconda-cluster/environment.yml" created
...

```

List conda environments

To verify that the environment has been pushed to all nodes, use the `info` command:

```

$ acluster conda info -e
All nodes (x3) response:
# conda environments:
#
stats                /opt/anaconda/envs/stats
root                 *  /opt/anaconda

```

Python with Spark How-tos

These how-tos will show you how to run Python tasks on a Spark cluster using the PySpark module. These how-tos will also show you how to interact with data stored within HDFS on the cluster.

While these how-tos are not dependent on each other and can be accomplished in any order it is recommended that you begin with the *Overview of Spark, YARN and HDFS* first.

Overview of Spark, YARN and HDFS

[Spark](#) is an analytics engine and framework that is capable of running queries 100 times faster than traditional MapReduce jobs written in Hadoop. In addition to the performance boost, developers can write Spark jobs in Scala, Python and Java if they so desire. Spark can load data directly from disk, memory and other data storage technologies such as Amazon S3, Hadoop Distributed File System (HDFS), HBase, Cassandra, etc.

You can install Spark using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

Submitting Spark Jobs

Spark scripts are often developed interactively and can be written as a script file or as a Jupyter notebook file.

A Spark script can be submitted to a Spark cluster using various methods:

- Running the script directly on the head node.
- Using the [spark-submit](#) script in either Standalone mode or with the YARN resource manager
- Interactively in an IPython shell or Jupyter Notebook on the cluster

To run a script on the head node, simply execute `python example.py` on the cluster.

Note: that in order to launch Jupyter Notebook on the cluster, the plugin must already be installed. See the [Plugins](#) documentation for more information.

Working with Data in HDFS

Moving data in and around HDFS can be difficult. If you need to move data from your local machine to HDFS, from Amazon S3 to HDFS, from Amazon S3 to Redshift, from HDFS to Hive and so on, we recommend using [odo](#), which is part of the [Blaze ecosystem](#). Odo efficiently migrates data from the source to the target through a network of conversions.

If you are unfamiliar with Spark and/or SQL, we recommend using [Blaze](#) to express selections, aggregations, group-bys, etc. in a dataframe-like style. Blaze provides Python users with a familiar interface to query data that exists in different data storage systems.

How to Run a Spark Standalone Job

Overview

This is a minimal Spark script that imports PySpark, initializes a SparkContext and performs a distributed calculation on a Spark cluster in standalone mode.

Who is this for?

This how-to is for users of a Spark cluster that has been configured in standalone mode who wish to run Python code.

Spark Standalone Summary

1. *Before you start*
2. *Modifying the script*
3. *Running the job*
4. *Troubleshooting*
5. *Further information*

Before you start

To execute this example, download the `cluster-spark-basic.py` example script to the cluster node where you submit Spark jobs.

For this example, you'll need Spark running with the standalone scheduler. You can install Spark using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#). Some additional configuration might be necessary to use Spark in standalone mode.

Modifying the script

After downloading the `cluster-spark-basic.py` example script open the file in a text editor on your cluster. Replace `HEAD_NODE_HOSTNAME` with the hostname of the head node of the Spark cluster.

```
# cluster-spark-basic.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('spark://HEAD_NODE_HOSTNAME:7077')
conf.setAppName('spark-basic')
sc = SparkContext(conf=conf)

def mod(x):
    import numpy as np
    return (x, np.mod(x, 2))

rdd = sc.parallelize(range(1000)).map(mod).take(10)
print rdd
```

Let's analyze the contents of the `spark-basic.rst` example script. The first code block contains imports from PySpark.

The second code block initializes the `SparkContext` and sets the application name.

The third code block contains the analysis code that calculates the modulus of a range of numbers up to 1000 using the NumPy package and returns/prints the first 10 results.

Note: you may have to install NumPy with `acluster conda install numpy`.

Running the job

You can run this script by submitting it to your cluster for execution using `spark-submit` or by running this command

```
python cluster-spark-basic.py
```

The output from the above command shows the first ten values that were returned from the `cluster-spark-basic.py` script.

```
16/05/05 22:26:53 INFO spark.SparkContext: Running Spark version 1.6.0

[...]

16/05/05 22:27:03 INFO scheduler.TaskSetManager: Starting task 0.0 in stage 0.0 (TID_
↪0, localhost, partition 0,PROCESS_LOCAL, 3242 bytes)
16/05/05 22:27:04 INFO storage.BlockManagerInfo: Added broadcast_0_piece0 in memory_
↪on localhost:46587 (size: 2.6 KB, free: 530.3 MB)
16/05/05 22:27:04 INFO scheduler.TaskSetManager: Finished task 0.0 in stage 0.0 (TID_
↪0) in 652 ms on localhost (1/1)
16/05/05 22:27:04 INFO cluster.YarnScheduler: Removed TaskSet 0.0, whose tasks have_
↪all completed, from pool
16/05/05 22:27:04 INFO scheduler.DAGScheduler: ResultStage 0 (runJob at PythonRDD.
↪scala:393) finished in 4.558 s
16/05/05 22:27:04 INFO scheduler.DAGScheduler: Job 0 finished: runJob at PythonRDD.
↪scala:393, took 4.951328 s
[(0, 0), (1, 1), (2, 0), (3, 1), (4, 0), (5, 1), (6, 0), (7, 1), (8, 0), (9, 1)]
```

Troubleshooting

If something goes wrong consult the [FAQ / Known issues](#) page.

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

How to Run with the YARN resource manager

Overview

This script runs on the Spark cluster with the YARN resource manager and returns the hostname of each node in the cluster.

Who is this for?

This how-to is for users of a Spark cluster who wish to run Python code using the YARN resource manager.

Spark YARN Summary

1. *Before you start*

2. *Running the Job*
3. *Troubleshooting*
4. *Further information*

Before you start

To execute this example, download the `cluster-spark-yarn.py` example script to your cluster.

For this example, you'll need Spark running with the YARN resource manager. You can install Spark and YARN using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

Running the Job

Here is the complete script to run the Spark + YARN example in PySpark:

```
# cluster-spark-yarn.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-yarn')
sc = SparkContext(conf=conf)

def mod(x):
    import numpy as np
    return (x, np.mod(x, 2))

rdd = sc.parallelize(range(1000)).map(mod).take(10)
print rdd
```

Note: you may have to install NumPy with `cluster conda install numpy`.

Run the script on the Spark cluster with `spark-submit`. The output shows the first ten values that were returned from the `cluster-spark-basic.py` script.

```
16/05/05 22:26:53 INFO spark.SparkContext: Running Spark version 1.6.0

[...]

16/05/05 22:27:03 INFO scheduler.TaskSetManager: Starting task 0.0 in stage 0.0 (TID_
↳0, localhost, partition 0,PROCESS_LOCAL, 3242 bytes)
16/05/05 22:27:04 INFO storage.BlockManagerInfo: Added broadcast_0_piece0 in memory_
↳on localhost:46587 (size: 2.6 KB, free: 530.3 MB)
16/05/05 22:27:04 INFO scheduler.TaskSetManager: Finished task 0.0 in stage 0.0 (TID_
↳0) in 652 ms on localhost (1/1)
16/05/05 22:27:04 INFO cluster.YarnScheduler: Removed TaskSet 0.0, whose tasks have_
↳all completed, from pool
16/05/05 22:27:04 INFO scheduler.DAGScheduler: ResultStage 0 (runJob at PythonRDD.
↳scala:393) finished in 4.558 s
16/05/05 22:27:04 INFO scheduler.DAGScheduler: Job 0 finished: runJob at PythonRDD.
↳scala:393, took 4.951328 s
[(0, 0), (1, 1), (2, 0), (3, 1), (4, 0), (5, 1), (6, 0), (7, 1), (8, 0), (9, 1)]
```

Troubleshooting

If something goes wrong consult the [FAQ / Known issues](#) page.

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

How to perform a word count on text data in HDFS

Overview

This example counts the number of words in text files that are stored in HDFS.

Who is this for?

This how-to is for users of a Spark cluster who wish to run Python code using the YARN resource manager that reads and processes files stored in HDFS.

Spark Wordcount Summary

1. *Before you start*
2. *Load HDFS data*
3. *Running the Job*
4. *Troubleshooting*
5. *Further information*

Before you start

To execute this example, download the `cluster-spark-wordcount.py` example script and the `cluster-download-wc-data.py` script.

For this example, you'll need Spark running with the YARN resource manager and the Hadoop Distributed File System (HDFS). You can install Spark, YARN, and HDFS using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

You will also need valid [Amazon Web Services](#) (AWS) credentials.

Load HDFS data

First, we will load the sample text data into the HDFS data store. The following script will transfer sample text data (approximately 6.4 GB) from a public Amazon S3 bucket to the HDFS data store on the cluster.

Download the `cluster-download-wc-data.py` script to your cluster and Insert your Amazon AWS credentials in the `AWS_KEY` and `AWS_SECRET` variables.

```
import subprocess

AWS_KEY = ''
AWS_SECRET = ''

s3_path = 's3n://{0}:{1}@blaze-data/enron-email'.format(AWS_KEY, AWS_SECRET)
cmd = ['hadoop', 'distcp', s3_path, 'hdfs:///tmp/enron']
subprocess.call(cmd)
```

Note: The `hadoop distcp` command might cause HDFS to fail on smaller instance sizes due to memory limits.

Run the `cluster-download-wc-data.py` script on the Spark cluster.

```
python cluster-download-wc-data.py
```

After a few minutes, the text data will be in the HDFS data store on the cluster and ready for analysis.

Running the Job

Download the `cluster-spark-wordcount.py` example script to your cluster. This script will read the text files downloaded in step 2 and count all of the words.

```
# cluster-spark-wordcount.py
from pyspark import SparkConf
from pyspark import SparkContext

HDFS_MASTER = 'HEAD_NODE_IP'

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-wordcount')
conf.set('spark.executor.instances', 10)
sc = SparkContext(conf=conf)

distFile = sc.textFile('hdfs://{0}:9000/tmp/enron/*/*.txt'.format(HDFS_MASTER))

nonempty_lines = distFile.filter(lambda x: len(x) > 0)
print 'Nonempty lines', nonempty_lines.count()

words = nonempty_lines.flatMap(lambda x: x.split(' '))

wordcounts = words.map(lambda x: (x, 1)) \
    .reduceByKey(lambda x, y: x+y) \
    .map(lambda x: (x[1], x[0])).sortByKey(False)

print 'Top 100 words:'
print wordcounts.take(100)
```

Replace the `HEAD_NODE_IP` text with the IP address of the head node.

Run the script on your Spark cluster using `spark-submit`. The output shows the top 100 words from the sample text data that were returned from the Spark script.

```

Troubleshooting

If something goes wrong consult the [FAQ / Known issues](#) page.

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

How to do Natural Language Processing

Overview

This example provides a simple PySpark job that utilizes the [NLTK library](#). NLTK is a popular Python package for natural language processing. This example will demonstrate the installation of Python libraries on the cluster, the usage of Spark with the YARN resource manager and execution of the Spark job.

Who is this for?

This how-to is for users of a Spark cluster who wish to run Python code using the YARN resource manager. This how-to will show you how to integrate third-party Python libraries with Spark.

Spark NLTK summary

1. *Before you start*
2. *Install NLTK*
3. *Running the Job*
4. *Troubleshooting*
5. *Further information*

Before you start

To execute this example, download the: `cluster-spark-nltk.py` example script or `cluster-spark-nltk.ipynb` example notebook.

For this example you'll need Spark running with the YARN resource manager. You can install Spark and YARN using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

Install NLTK

If you have permission to install packages with `acluster` you can install NLTK as a conda package.

```
acluster conda install nltk
```

You should see output similar to this from each node, which indicates that the package was successfully installed across the cluster:

```
Node "ip-10-140-235-89.ec2.internal":
  Successful actions: 1/1
Node "ip-10-154-10-144.ec2.internal":
  Successful actions: 1/1
Node "ip-10-31-96-152.ec2.internal":
  Successful actions: 1/1
```

In order to use the full NLTK library, you will need to download the data for the NLTK project. You can download the data on all cluster nodes by using the `acluster cmd` command.

```
acluster cmd 'sudo /opt/anaconda/bin/python -m nltk.downloader -d /usr/share/nltk_
↳data all'
```

After a few minutes you should see output similar to this.

```
Execute command "sudo /opt/anaconda/bin/python -m nltk.downloader -d /usr/share/nltk_
↳data all" target: "*" cluster: "d"
  All nodes (x3) response: [nltk_data] Downloading collection 'all'
[nltk_data] |
[nltk_data] | Downloading package abc to /usr/share/nltk_data...
[nltk_data] | Unzipping corpora/abc.zip.
[nltk_data] | Downloading package alpino to /usr/share/nltk_data...
[nltk_data] | Unzipping corpora/alpino.zip.
[nltk_data] | Downloading package biocreative_ppi to
[nltk_data] | /usr/share/nltk_data...
....
[nltk_data] | Unzipping models/bllip_wsj_no_aux.zip.
[nltk_data] | Downloading package word2vec_sample to
[nltk_data] | /usr/share/nltk_data...
[nltk_data] | Unzipping models/word2vec_sample.zip.
[nltk_data] |
[nltk_data] Done downloading collection all
```

Running the Job

Here is the complete script to run the Spark + NLTK example in PySpark.

```
# cluster-spark-nltk.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-nltk')
sc = SparkContext(conf=conf)

data = sc.textFile('file:///usr/share/nltk_data/corpora/state_union/1972-Nixon.txt')

def word_tokenize(x):
    import nltk
    return nltk.word_tokenize(x)

def pos_tag(x):
```

(continues on next page)

(continued from previous page)

```
import nltk
return nltk.pos_tag([x])

words = data.flatMap(word_tokenize)
print words.take(10)

pos_word = words.map(pos_tag)
print pos_word.take(5)
```

Let's walk through the above code example. First, we will create a `SparkContext`. Note that Anaconda for cluster management will not create a `SparkContext` by default. In this example, we use the YARN resource manager.

```
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-nltk')
sc = SparkContext(conf=conf)
```

After a `SparkContext` is created, we can load some data into Spark. In this case, the data file is from one of the example documents provided by NLTK.

```
data = sc.textFile('file:///usr/share/nltk_data/corpora/state_union/1972-Nixon.txt')
```

Next, we write a function that imports `nltk` and calls `nltk.word_tokenize`. The function is mapped to the text file that was read in the previous step.

```
def word_tokenize(x):
    import nltk
    return nltk.word_tokenize(x)

words = data.flatMap(word_tokenize)
```

We can confirm that the `flatMap` operation worked by returning some of the words in the dataset.

```
print words.take(10)
```

Finally, NTLK's [POS-tagger](#) can be used to find the part of speech for each word.

```
def pos_tag(x):
    import nltk
    return nltk.pos_tag([x])

pos_word = words.map(pos_tag)
print pos_word.take(5)
```

Run the script on the Spark cluster using the `spark-submit` script. The output shows the words that were returned from the Spark script, including the results from the `flatMap` operation and the POS-tagger.

```
Using Spark's default log4j profile: org/apache/spark/log4j-defaults.properties
15/06/13 05:14:29 INFO SparkContext: Running Spark version 1.4.0

[...]

['Address',

```

Troubleshooting

If something goes wrong consult the *FAQ / Known issues* page.

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

For more information on NLTK see the *NLTK book* <<http://www.nltk.org/book/>>.

How to do Image Processing with GPUs

Overview

To demonstrate the capability of running a distributed job in PySpark using a GPU, this example uses [NumbaPro](#) and the CUDA platform for image analysis. This example executes 2-dimensional FFT convolution on images in grayscale and compares the execution time of CPU-based and GPU-based calculations.

Who is this for?

This how-to is for users of a Spark cluster who wish to run Python code using the YARN resource manager. This how-to will show you how to integrate third-party Python libraries with Spark.

Image processing summary

1. *Before you start*
2. *Install dependencies*
3. *Load data into HDFS*
4. *Running the Job*

- 5. *Troubleshooting*
- 6. *Further information*

Before you start

For this example, you'll need Spark running with the YARN resource manager. You can install Spark and YARN using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

You will also need valid [Amazon Web Services \(AWS\)](#) credentials in order to download the example data.

For this example, we recommend the use of the GPU-enabled AWS instance type `g2.2xlarge` and the AMI `ami-12fd8178` (us-east-1 region), which has CUDA 7.0 and the NVIDIA drivers pre-installed. An example profile (to be placed in `~/.acluster/profiles.d/gpu_profile.yaml`) is shown below:

```
name: gpu_profile
node_id: ami-12fd8178 # Ubuntu 14.04, Cuda 7.0, us-east-1 region
node_type: g2.2xlarge
num_nodes: 4
provider: aws_east
user: ubuntu
```

To execute this example, download the: `spark-numbapro.py` example script or `spark-numbapro.ipynb` example notebook.

If you wish to use the `spark-numbapro.ipynb` example notebook the Jupyter Notebook plugin can be installed on the cluster using the following command:

```
acluster install notebook
```

Once the Jupyter Notebook plugin is installed, you can view Jupyter Notebook in your browser using the following command:

```
acluster open notebook
```

Install dependencies

If you have permission to install packages with `acluster` you can install the required packages on all nodes using the following command.

```
acluster conda install scipy matplotlib numbapro PIL
```

Load data into HDFS

First, we will load the sample text data into the HDFS data store. The following script will transfer sample image data (approximately 1.1 GB) from a public Amazon S3 bucket to the HDFS data store on the cluster.

Download the `cluster-download-data.py` script to your cluster and insert your Amazon AWS credentials in the `AWS_KEY` and `AWS_SECRET` variables.

```
import subprocess

AWS_KEY = 'YOUR_AWS_KEY'
AWS_SECRET = 'YOUR_AWS_SECRET'
```

(continues on next page)

(continued from previous page)

```
s3_path = 's3n://{0}:{1}@blaze-data/dogs-cats-img/images'.format(AWS_KEY, AWS_SECRET)
cmd = ['hadoop', 'distcp', s3_path, 'hdfs:///tmp/dogs-cats']
subprocess.call(cmd)
```

Note: The `hadoop distcp` command might cause HDFS to fail on smaller instance sizes due to memory limits.

Run the `cluster-download-data.py` script on the cluster.

```
python cluster-download-data.py
```

After a few minutes, the image data will be in the HDFS data store on the cluster and ready for analysis.

Running the Job

Run the `spark-numbapro.py` script on the Spark cluster using `spark-submit`. The output shows the image processing execution times for the CPU-based vs. GPU-based calculations.

```
54.164.123.31: Using Spark's default log4j profile: org/apache/spark/log4j-defaults.

Troubleshooting

If something goes wrong consult the [FAQ / Known issues](#) page.

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

For more information on NumbaPro see the [NumbaPro documentation](#).

Using Anaconda with Cloudera CDH

NOTE: This page is superseded, please see <https://docs.continuum.io/anaconda-scale/cloudera-cdh>

There are two methods of using Anaconda on an existing cluster with [Cloudera CDH](#), Cloudera's Distribution Including Apache Hadoop: 1) the [Anaconda parcel for Cloudera CDH](#), and 2) Anaconda for cluster management. The instructions below describe how to uninstall the Anaconda parcel on a CDH cluster and transition to Anaconda for cluster management.

Uninstalling the Anaconda parcel

If the Anaconda parcel is installed on the CDH cluster, use the following steps to uninstall the parcel. Otherwise, you can skip to the next section.

1. From the Cloudera Manager Admin Console, click the Parcels indicator in the top navigation bar.
2. Click the `Deactivate` button to the right of the Anaconda parcel listing.
3. Click `OK` on the Deactivate prompt to deactivate the Anaconda parcel and restart Spark and related services.
4. Click the arrow to the right of the Anaconda parcel listing and choose `Remove From Hosts`, which will prompt with a confirmation dialog.
5. The Anaconda parcel has been removed from the cluster nodes.

For more information about managing Cloudera parcels, refer to the [Cloudera documentation](#).

Using Anaconda for cluster management

Anaconda for cluster management provides additional functionality, including the ability to manage multiple conda environments and packages (including Python and R) alongside an existing CDH cluster.

1. Configure the nodes with Anaconda for cluster management using the [Bare-metal Cluster Setup instructions](#).
2. During this process, you will create a profile and provider that describes the cluster.
3. Provision the cluster using the following command, replacing `cluster-cdh` with the name of your cluster and `profile-cdh` with the name of your profile:

```
$ acluster create cluster-cdh -p profile-cdh
```

4. You can submit Spark jobs along with the `PYSPARK_PYTHON` environment variable that refers to the location of Anaconda, for example:

```
$ PYSPARK_PYTHON=/opt/anaconda/bin/python spark-submit pyspark_script.py
```

Support

Priority support

Support is included with the purchase of an Anaconda subscription. Please contact Anaconda for cluster management support at ac_support@anaconda.com.

Report a bug

If you think you may have encountered a bug, please contact Anaconda for cluster management support at ac_support@anaconda.com.

Additional nodes

With the unlicensed, unsupported version of Anaconda for cluster management, you can create and manage up to four cluster nodes. To request a license to manage more cluster nodes, please contact your account representative or sales@anaconda.com.

Training and consulting

Training and consulting is available for Anaconda for cluster management and all Anaconda products. For more information, please contact your account representative or sales@anaconda.com.

FAQ / Known issues

- *[Product FAQ](#)*
- *[Technical FAQ](#)*
- *[Troubleshooting FAQ](#)*
- *[Known Issues](#)*

Product FAQ

Does Anaconda for cluster management work with a cluster that already has a managed Spark/Hadoop stack?

Yes, Anaconda for cluster management can be installed alongside enterprise Hadoop distributions such as Cloudera CDH or Hortonworks HDP and can be used to manage Python and R conda packages and environments across a cluster.

Does Anaconda for cluster management offer integration with Anaconda Repository or Anaconda Cloud?

Yes, conda packages can be installed from Anaconda Repository or [Anaconda Cloud](#) by using channel specifications. Refer to the documentation regarding *[Installing packages from channels](#)* for more details.

Which cloud providers does Anaconda for cluster management support?

Currently Anaconda for cluster management offers full support for Amazon Elastic Compute Cloud (EC2). Other providers such as Microsoft Azure, Google Cloud Platform, Rackspace, and others are on our roadmap. If you are interested in a cloud provider that is not listed here, please contact us at sales@anaconda.com.

Can I use Anaconda for cluster management with a different cloud provider?

Yes, you can manually create instances on another cloud provider, then provision the nodes as if you were using a bare-metal cluster. Refer to the [Bare-metal Cluster Setup](#) documentation for more information.

Does Anaconda for cluster management support Amazon EMR?

Anaconda for cluster management does not support Amazon Elastic MapReduce (EMR), which provides a managed Hadoop framework in the cloud. Anaconda for cluster management can be used to manage conda packages and environments across a cluster. Anaconda for cluster management does support Amazon EC2.

Technical FAQ**Which versions of Python does Anaconda for cluster management support?**

Some of the plugins have dependencies that require the use of Python 2. Therefore, by default, Anaconda for cluster management installs Miniconda with Python 2 into the root conda environment.

However, you can easily create a new conda environment on the cluster with Python 3, or you can specify a different root version of Anaconda/Miniconda in the profile.

Which network ports need to be accessible from the client machine and cluster nodes?

From the client machine to the cluster nodes, you will need access to ports 22, 4505, and 4506 to provision the cluster via SSH and Salt. For communication between the cluster nodes, Salt uses ports 4505 and 4506.

Can I use Anaconda for cluster management with iptables and SELinux?

Yes, you can customize the security behavior of Anaconda for cluster management when creating or provisioning a cluster using the Security settings in the profile. Refer to the [Profile settings](#) documentation for more information.

Troubleshooting FAQ**Errors when creating or provisioning a cluster**

Verify the following:

- The contents of your SSH private key are correct (and set to 600 permissions on Mac/Linux)
- The user name in your profile (e.g., `user: ubuntu`) is defined correctly
- Profile settings are defined correctly in `~/.acluster/profiles.d/<profile_name>.yaml`
- Provider settings are defined correctly in `~/.acluster/providers.yaml`

Known Issues**No matching SLS error (Salt)**

When installing a plugin during cluster creation/provisioning or using the `acluster install` command, you might receive an error similar to:

```
===== Standard output =====
ip-10-144-206-102.ec2.internal:
- No matching sls found for 'cdh5.hdfs' in env 'base'
=====
```

(continues on next page)

(continued from previous page)

```
Fatal error: One or more hosts failed while executing task 'parallel_sudo'

Aborting.
One or more hosts failed while executing task 'parallel_sudo'
```

This is a known issue with Salt that periodically occurs. You can reprovision or reinstall the plugin that failed, and the installation should succeed.

Theading error when creating a cluster

When creating/provisioning a cluster, you might receive an error similar to:

```
Uploading formulas
INFO: Uploading formulas to head
Syncing formulas
INFO: Syncing formulas across the cluster
Done
Exception in thread Thread-6 (most likely raised during interpreter shutdown):
Exception in thread Thread-8 (most likely raised during interpreter shutdown):
```

This is a known issue with Paramiko/Fabric. You can safely disregard this message. This issue was resolved in Anaconda for cluster management 1.3.1.

Release notes

Below is a summary of features, bug fixes, and improvements for each Anaconda for cluster management release.

Anaconda for cluster management 1.4.4

Note: This is the last feature release of Anaconda for cluster management. Anaconda for cluster management has been replaced by [Anaconda Scale](#).

Backend improvements:

- Use full paths for system commands

Anaconda for cluster management 1.4.3

Backend improvements:

- Fix license check and support information

Anaconda for cluster management 1.4.2

Features:

- Updates to examples in documentation

Backend improvements:

- Improved group configuration/detection on RHEL/CentOS
- Enabled configuration of `anaconda` group name

Anaconda for cluster management 1.4.1

Features:

- Renamed `distributed` plugin to `dask`
- Enabled `notebook` and `dask` plugins to be installed alongside existing Hadoop installations

- Added `conda` profile plugin setting for `ssl_verify`

Anaconda for cluster management 1.4.0

Features:

- Added setting for `channel_alias` for improved integration with Anaconda Repository

Bug Fixes:

- Fixed provisioning on Windows client machines
- Fixed issue with profile setting for `conda` access control lists
- Fixed issue with certain plugin status checks
- Fixed issue with Storm plugin installation

Backend improvements:

- Improved management and configurability of `distributed` plugin
- Updated version of Apache Libcloud dependency (0.20.1)
- Updated to accept new license format (backwards compatible with existing licenses)
- Removed deprecated `acluster submit` command due to inconsistencies with environments
- Removed `acluster defaultenv` and `acluster setenv` commands due to inconsistencies with environments
- Consolidated sample profile to a single profile

Anaconda for cluster management 1.3.3

Bug Fixes:

- Fixed SSH private key permissions check

Backend improvements:

- Implemented Salt ACL functionality
- Implemented Salt PAM authentication
- Removed sudo requirement after install

Anaconda for cluster management 1.3.2

Bug Fixes:

- Fixed installation prefix and default channel documentation and tests

Backend improvements:

- Improved detection of plugin installations and plugin status messages

Anaconda for cluster management 1.3.1

Features:

- Updated plugin: Spark 1.6
- Added option to disable creation of `/etc/profile.d/conda.sh` on cluster nodes

Bug Fixes:

- Fixed R path for Jupyter Notebook
- Fixed issue with Amazon EC2 block device mapping

- Fixed issue with configuration of default conda channels
- Improved warnings for misconfigured SSH keys
- Improved error message when AWS Key Pair is missing

Backend improvements:

- Added configurable download URLs for plugins (used for airgap installations): Elasticsearch, Logstash, Kibana, Storm
- Added deprecated warning for `acluster submit` command due to inconsistencies with environments
- Added detection for enterprise Hadoop installations and warns before installing conflicting services
- Configured HDFS for short-circuit reads by default
- Pinned versions of dependencies in conda recipe

Anaconda for cluster management 1.3.0

Features:

- Simplified bare-metal cluster setup using profile/provider instead of clusters.d
- Added ability to specify conda packages and environments in profile plugin settings
- Switched to system-wide `.condarc` file for users on cluster nodes
- Added centralized logging via Elasticsearch, Logstash, and Kibana plugins
- Added `--no-browser` option for `acluster open` command
- Added license information to `acluster info`
- Removed optional `security_group` setting from `providers.yaml` template and documentation
- Added `vpc_id` setting for Amazon EC2 to use with default security group
- Improved documentation for bare-metal and cloud-based cluster creation
- Added more information about requirements, FAQs, and known issues to documentation

Bug Fixes:

- Improved error messages for cloud providers, security groups, and when no clusters are defined
- Fixed error when command output contained Unicode characters
- Fixed repeated prompts when installing multiple plugins

Backend improvements:

- Added test for SSH connectivity during bare-metal cluster creation
- Added detection/removal of orphaned clusters upon `acluster destroy`
- Added detection/installation of missing `sudo/bzip2` packages upon cluster creation

Anaconda for cluster management 1.2.2

Features:

- Moved bare metal cluster setup to profile and provider files
- Ability to specify private IPs for VPC clusters on Amazon EC2

Anaconda for cluster management 1.2.1

Features:

- Updated plugin: Spark 1.5.1
- Consistent output when listing clusters and profiles
- New blog post and updated documentation

Bug Fixes:

- Removed duplicate error messages
- Fixed notebook plugin formulas

Anaconda for cluster management 1.2.0

Features:

- Dedicated salt/supervisor environments
- New cluster profile (no nesting)
- Documentation updates
- Improvements to CLI output

Bug Fixes:

- Storm plugin
- Notebook plugin
- Logstash plugin
- Kibana plugin
- Elasticsearch plugin
- Windows Fixes: push/submit

Backend improvements:

- Refactor status/stop/restart and plugin loading
- Refactor connection object
- Multiple backends (initial work)

Anaconda for cluster management 1.1.0

- Improved Jenkins testing
- Added Storm plugin
- Added Elasticsearch/Logstash/Kibana plugins (ELK stack)
- Added Dask plugin
- Fixes for single-node installations
- Profile updates
- Add setting for AWS Tags
- Added security options (SELinux/iptables)
- Added setting for notebook password

Anaconda for cluster management 1.0.0

- CLI rewrite
- Aggregated and improved CLI messaging

- Backend library refactoring
- Salt-packaging refactoring
- Easier bare-metal installation
- Added option for streaming output
- Fixed issue with Ganglia on Ubuntu
- Windows/libcloud Compatibility
- Added licensing with new CLI
- Conda remote fixes
- Install Anaconda/Miniconda from custom url

Glossary

Anaconda A downloadable free, open source, high performance, optimized Python and R distribution with 100+ packages plus access to easily installing an additional 620+ popular open source packages for data science including advanced and scientific analytics. It also includes `conda`, an open source package, dependency and environment manager. Thousands more open source packages can be installed with the `conda` command. Available for Windows, OS X and Linux, all versions are supported by the community.

Bare-metal cluster On-site or in-house machines, collections of virtual machines (Vagrant, Docker, etc.), or previously instantiated cloud nodes.

Cloud-based cluster A cluster that consists of machines in a cloud provider such as Amazon EC2.

Cluster A group of computers that work in parallel to perform a single task. Also called “parallel computing” since the compute nodes can perform their operations in parallel.

Client machine The laptop or workstation that contains Anaconda for cluster management and manages the cluster nodes.

Cluster file The file that defines the configuration including the location of the head node, compute nodes, and authentication/configuration information.

Compute node The machines managed by the head node that all work together to complete a single task.

Conda Conda is an open source package management system and environment management system for installing multiple versions of software packages and their dependencies and switching easily between them. It works on Windows, Mac, and Linux. It was created for Python packages, but is able to package and distribute any software. Conda is included in all versions of Anaconda, Anaconda Server, and Miniconda.

Head node A system configured to act as the intermediary between the cluster and the outside network. Can also be referred to as the master or edge node.

Miniconda A minimal or “bootstrap” version of Anaconda. Installs only what you need to get conda running, including Python, conda, and its dependencies.

PEM key Privacy enhanced electronic mail file, originally for email and now a general file format for cryptographic keys. In Anaconda for cluster management, this is used for cloud-based clusters and can be obtained from the cloud provider.

Plugin In Anaconda for cluster management, plugins are analytics engines and management services that can be installed on a cluster.

Profile A configuration file that defines how a cluster should be configured. It contains information about the number and types of cluster nodes, plugins, and other settings.

Provider Configuration file that defines settings for cloud or bare metal providers. A provider is referenced by a profile and used to provision resources.

4.4.4 Anaconda Launcher

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it.

Anaconda Launcher is now deprecated

As of Anaconda 4.0, Anaconda Launcher has been replaced by *Anaconda Navigator*. This section has been left in place as a reference for users of earlier versions of Anaconda. Some users who have upgraded from an earlier version may have both Navigator and Launcher installed, which is harmless.

Launcher can be uninstalled with a single command:

```
conda remove launcher
```

Anaconda Launcher commands

Refresh Application List

Click on **Launcher** to refresh the apps display.

Install Listed Application

Click on the green **Install** button to install the desired app.

Launch Application

Click on the **Launch** button to launch the application.

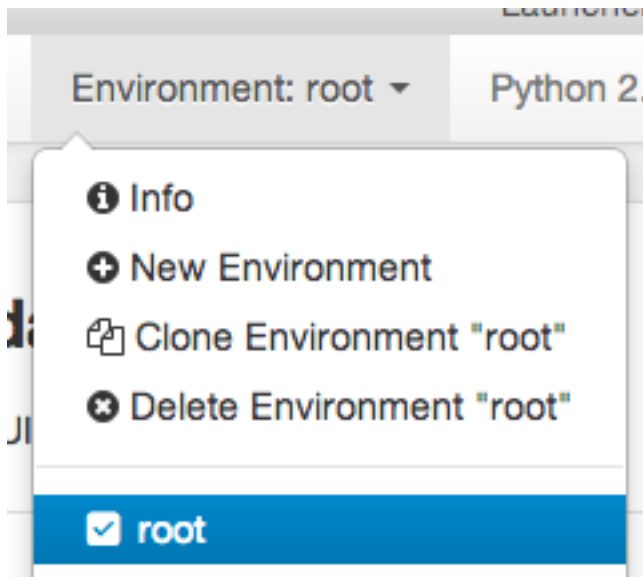

Update Application

Click on the **Update** button to update the application.

Change Environments

To change the current Environment, click on the **Environment:** pull down menu item and select the desired environment to make it active.

Environment Information

To get a summary of the current environment, click on the **Environment:** menu item and select info.

You can also get a summary of the environment by click on the **Python version** menu item.

Create New Environment

To create a new environment, click on the **Environment:** menu item and select **New Environment**.

When the **Create New Environment** dialog appears, enter the name of the new environment, select the desired **Python Version**, and click **Submit**.

Clone Environment

To clone an environment, click on the **Environment:** menu item and select **Clone Environment**.

When the **Clone Environment** dialog appears, enter the name of the new environment and click **Submit**.

Clone Environment root

x

New Environment Name

Cancel

Submit

Delete Environment

To delete an environment, click on the **Environment:** menu item and select **Delete Environment**.
When the **Confirm Delete Environment** dialog appears, click **Yes** to delete the environment.

Confirm Delete Environment

Are you sure you want to delete environment alpuq?

Cancel

Yes

Manage Channels

To manage your current package channels, click on the **Manage Channels** menu item.

Manage Conda Channels x

Enter a Binstar username or a URL. Conda will search these channels for packages. If the channel `defaults` is not present, Conda will not search the default channels.

[Online configuration help](#)

Add Channel

defaults
x

tpowell
x

Cancel
Submit

Add Channel

Enter your channel into the text field to the left of the **Add Channel** button.

Click on the **Add Channel** to add your channel to your `.condarc` file.

Remove Channel

Click on the **x** button to the right of the channel name you would like to remove.

Click **Cancel** to removed the changes to your channels.

Click **Submit** to save the channel updates.

Anaconda Launcher Info

For Anaconda Launcher details, click on the version number in the upper right hand corner of the Anaconda Launcher Window.

Other Helpful Links

Along the right side of the launcher are some helpful links to additional documentation and various Anaconda and Anaconda Sponsored websites.

4.4.5 Anaconda Scale

Distributed Computing

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it.

Anaconda Scale provides functionality to easily deploy Anaconda® packages and a distributed computation framework across a cluster. It helps you manage multiple conda environments and packages—including Python and R—on cluster nodes.

Anaconda Scale provides different options for deploying Anaconda on a cluster, including:

- Centrally managed installation of Anaconda, including multiple environments such as Python and R
- Anaconda parcel for Cloudera CDH, including custom-generated parcels
- Deployment of conda packages and environments with Spark jobs

Features

- Easily install Anaconda—including [Anaconda Accelerate](#)—across multiple cluster nodes
- Provision distributed compute services with Dask
- Perform interactive, distributed computations with single-user Jupyter Notebook
- Easily launch and configure a cloud-based cluster on Amazon EC2

Compatibility

Anaconda Scale can be used with distributed computation frameworks such as Spark or Dask and works alongside enterprise Hadoop distributions such as Cloudera CDH or Hortonworks HDP. Anaconda Scale has been tested with the following Hadoop distributions and Spark versions:

- Cloudera CDH 5.3.x through 5.11.x
- Hortonworks HDP 2.2.x through 2.6.x (with Apache Ambari 2.2.x and 2.4.x)
- Spark 1.3.x through 2.0.x

License

Anaconda Scale is available with [Anaconda Enterprise](#). If you would like to use Anaconda Scale with a cluster on a bare-metal, on-premises, or cloud-based cluster, please [contact us](#).

Using Scale

Installation

Anaconda Scale is installed and managed using the Anaconda platform installer, Anaconda Adam. For more information on installation, security, account, network and other Anaconda Scale requirements, see the [system requirements for Anaconda Adam](#). For more information about the installation process, see [the Anaconda Adam installation instructions](#).

After installing Anaconda Adam and provisioning a cluster, you can install a centrally managed version of Anaconda—including [Anaconda Accelerate](#)—on all of the cluster nodes using:

```
$ adam scale -n <cluster-name> cluster install
```

To install Dask and Distributed and then start Distributed workers on all of the cluster nodes, use:

```
$ adam scale -n <cluster-name> dask install
```

To install a single-user Jupyter Notebook server on the head node of the cluster, use:

```
$ adam scale -n <cluster-name> notebook install
```

User guide

Using Anaconda Scale with Anaconda Adam, you can create and manage conda packages, including Python and R, in multiple conda environments across your nodes. You can prepend `adam scale` to a subset of familiar conda commands to install and manage conda packages and environments across a cluster.

```
$ adam scale -n cluster conda --help
Usage: adam conda [OPTIONS] COMMAND [ARGS]...

Options:
  -h, --help            Show this message and exit.

Commands:
  create  Create conda environment
  info    Get information about conda installation
  install Install package(s)
  list    List conda packages
  remove  Remove package(s)
  update  Update package(s)
```

By default, the root conda environment is installed in `/opt/continuum/anaconda` on all of the cluster nodes, which can be configured for a different location. You can manage multiple conda environments across the same cluster, such as Python 2, Python 3 and R, without affecting the framework installation of Python on the cluster nodes.

Getting started

You can get started with Anaconda Scale by using Anaconda Adam, the Anaconda platform installer. See the [Anaconda Adam documentation](#) for more information.

With Anaconda Adam, you can install Anaconda Scale on a bare-metal cluster or existing cloud-based cluster. You can also use Anaconda Scale to easily launch and provision a cloud-based cluster with Anaconda. See the [Anaconda Adam installation instructions](#) for more information.

Tasks

- [General functions](#)
- [Using Anaconda with Cloudera CDH](#)
- [Configuring Anaconda with Spark](#)

Cheatsheet

Download the `Scale cheat sheet` (48 KB PDF) for a quick guide to using Anaconda Scale.

General functions

Installing conda packages

Install conda packages on the cluster nodes using `adam scale conda install`.

EXAMPLE: To install NumPy and pandas and their dependencies into the root conda environment on a cluster named `cluster`:

```
$ adam scale -n cluster conda install numpy pandas
All nodes (x4) response:
{
  "actions": {
    "LINK": [
      "mkl-11.3.3-0 /opt/continuum/anaconda/pkgs 1",
      "openssl-1.0.2h-1 /opt/continuum/anaconda/pkgs 1",
      "sqlite-3.13.0-0 /opt/continuum/anaconda/pkgs 1",
      "zlib-1.2.8-3 /opt/continuum/anaconda/pkgs 1",
      "python-2.7.11-5 /opt/continuum/anaconda/pkgs 1",
      "conda-env-2.5.1-py27_0 /opt/continuum/anaconda/pkgs 1",
      "numpy-1.11.0-py27_2 /opt/continuum/anaconda/pkgs 1",
      "pycosat-0.6.1-py27_1 /opt/continuum/anaconda/pkgs 1",
      "pytz-2016.4-py27_0 /opt/continuum/anaconda/pkgs 1",
      "pyyaml-3.11-py27_4 /opt/continuum/anaconda/pkgs 1",
      "requests-2.10.0-py27_0 /opt/continuum/anaconda/pkgs 1",
      "ruamel_yaml-0.11.7-py27_0 /opt/continuum/anaconda/pkgs 1",
      "setuptools-23.0.0-py27_0 /opt/continuum/anaconda/pkgs 1",
      "six-1.10.0-py27_0 /opt/continuum/anaconda/pkgs 1",
      "wheel-0.29.0-py27_0 /opt/continuum/anaconda/pkgs 1",
      "conda-4.1.4-py27_0 /opt/continuum/anaconda/pkgs 1",
      "pip-8.1.2-py27_0 /opt/continuum/anaconda/pkgs 1",
      "python-dateutil-2.5.3-py27_0 /opt/continuum/anaconda/pkgs 1",
      "pandas-0.18.1-np111py27_0 /opt/continuum/anaconda/pkgs 1"
    ],
    "PREFIX": "/opt/continuum/anaconda",
  },
  "success": true
}
```

Creating conda environments

Create multiple conda environments on the cluster nodes using `adam scale conda create`.

EXAMPLE: To create a conda environment called `py3` with Python 3 on a cluster named `cluster`:

```
$ adam scale -n cluster conda create -n py3 python=3
All nodes (x4) response:
{
  "actions": {
    "LINK": [
```

(continues on next page)

(continued from previous page)

```

        "openssl-1.0.2h-1 1 None",
        "readline-6.2-2 1 None",
        "sqlite-3.13.0-0 1 None",
        "tk-8.5.18-0 1 None",
        "xz-5.2.2-0 1 None",
        "zlib-1.2.8-3 1 None",
        "python-3.5.1-5 1 None",
        "setuptools-23.0.0-py35_0 1 None",
        "wheel-0.29.0-py35_0 1 None",
        "pip-8.1.2-py35_0 1 None"
    ],
    "PREFIX": "/opt/continuum/anaconda/envs/py3",
    "SYMLINK_CONDA": [
        "/opt/continuum/anaconda"
    ],
},
"success": true
}

```

Updating conda packages

Update conda packages on the cluster nodes using `adam scale conda update`.

EXAMPLE: To update pandas and its dependencies in the root conda environment on a cluster named `cluster`:

```

$ adam scale -n cluster conda update pandas
All nodes (x4) response:
{
  "actions": {
    "LINK": [
      "pandas-0.18.1-np111py27_0 1 None"
    ],
    "PREFIX": "/opt/continuum/anaconda",
    "SYMLINK_CONDA": [
      "/opt/continuum/anaconda"
    ],
    "UNLINK": [
      "pandas-0.18.0-np111py27_0"
    ],
  },
  "success": true
}

```

Removing conda packages or environments

Remove conda packages on the cluster nodes using `adam scale conda remove`.

EXAMPLE: To remove pandas from the root conda environment on a cluster named `cluster`:

```

$ adam scale -n cluster conda remove pandas
All nodes (x4) response:
{
  "actions": {
    "PREFIX": "/opt/continuum/anaconda",

```

(continues on next page)

(continued from previous page)

```

    "UNLINK": [
        "pandas-0.18.1-np111py27_0"
    ],
},
"success": true
}

```

Remove conda environments on the cluster nodes using `adam scale conda remove`.

EXAMPLE: To remove an environment called `py3` on a cluster named `cluster`:

```

$ adam scale -n cluster conda remove -n py3 --all
All nodes (x4) response:
{
  "actions": {
    "PREFIX": "/opt/continuum/anaconda/envs/py3",
    "UNLINK": [
      "openssl-1.0.2j-0",
      "pip-8.1.2-py35_0",
      "python-3.5.2-0",
      "readline-6.2-2",
      "setuptools-27.2.0-py35_0",
      "sqlite-3.13.0-0",
      "tk-8.5.18-0",
      "wheel-0.29.0-py35_0",
      "xz-5.2.2-0",
      "zlib-1.2.8-3"
    ]
  },
  "success": true
}

```

Listing conda packages

List conda packages on the cluster nodes using `adam scale conda list`.

EXAMPLE: To list conda packages in the root conda environment on a cluster named `cluster`:

```

$ adam scale -n cluster conda list
All nodes (x4) response:
+-----+-----+-----+
| Package      | Version | Build  |
+-----+-----+-----+
| numpy         | 1.11.0  | py27_2 |
| conda-env     | 2.5.1   | py27_0 |
| tk            | 8.5.18  | 0      |
| pip           | 8.1.2   | py27_0 |
| readline      | 6.2     | 2      |
| setuptools    | 23.0.0  | py27_0 |
| openssl       | 1.0.2h  | 1      |
| pycosat       | 0.6.1   | py27_1 |
| python-dateutil | 2.5.3   | py27_0 |
| sqlite        | 3.13.0  | 0      |
| pytz          | 2016.4  | py27_0 |
| mkl           | 11.3.3  | 0      |

```

(continues on next page)

(continued from previous page)

yaml	0.1.6	0	
ruamel_yaml	0.11.7	py27_0	
zlib	1.2.8	3	
pyyaml	3.11	py27_4	
requests	2.10.0	py27_0	
wheel	0.29.0	py27_0	
python	2.7.11	5	
conda	4.1.4	py27_0	
pycrypto	2.6.1	py27_0	
six	1.10.0	py27_0	
+-----+-----+-----+			

Getting conda information

View information about the conda installation on the cluster nodes using `adam scale conda info`.

EXAMPLE: To view information about the root conda environment on a cluster named `cluster`:

```
$ adam scale -n cluster conda info
All nodes (x4) response:
Current conda install:

    platform : linux-64
    conda version : 4.1.4
    conda-env version : 2.5.1
    conda-build version : not installed
    python version : 2.7.11.final.0
    requests version : 2.10.0
    root environment : /opt/continuum/anaconda (writable)
    default environment : /opt/continuum/anaconda
    envs directories : /opt/continuum/anaconda/envs
    package cache : /opt/continuum/anaconda/pkgs
    channel URLs : https://repo.anaconda.com/pkgs/free/linux-64/
                  https://repo.anaconda.com/pkgs/free/noarch/
                  https://repo.anaconda.com/pkgs/pro/linux-64/
                  https://repo.anaconda.com/pkgs/pro/noarch/
    config file : None
    offline mode : False
    is foreign system : False
```

Or to view a list of conda environments on the cluster nodes:

```
$ adam scale -n cluster conda info -e
All nodes (x4) response:
# conda environments:
#
py27                /opt/continuum/anaconda/envs/py27
py35                /opt/continuum/anaconda/envs/py35
r                   /opt/continuum/anaconda/envs/r
root                * /opt/continuum/anaconda
```

Managing conda with environment definition files

Manage conda environments on the cluster nodes using `adam scale env`:

```
$ adam scale -n cluster env
Usage: adam scale env [OPTIONS] COMMAND [ARGS]...
```

Options:

```
-h, --help Show this message and exit.
```

Commands:

```
create Create conda environment
list List conda environments
remove Remove conda environment
update Update conda environment
```

This functionality uses `conda-env` and conda environment environment definition–YAML–files.

EXAMPLE: The following `environment.yml` file describes a conda environment named `my-env` with Python 2.7 and additional packages:

```
name: my-env
channels:
- defaults
dependencies:
- python=2.7.*
- bokeh
- dask
- distributed
- pandas
```

Use `adam scale env create` to create a conda environment based on the above conda environment definition file `environment.yml`:

```
$ adam scale -n cluster env create -f environment.yml
All nodes (x4) response:
```

```

(continued from previous page)

```

        "LINK",
        "SYMLINK_CONDA"
    ]
},
"success": true
}

```

NOTE: The command `adam scale env create` is compatible only with conda dependencies and ignores any pip or other non-conda dependencies that are specified in the conda environment definition file.

Use `adam scale env list` to list conda environments on the cluster:

```

$ adam scale -n cluster env list
All nodes (x4) response:
# conda environments:
#
my-env                /opt/continuum/anaconda/envs/my-env
root                  * /opt/continuum/anaconda

```

Use `adam scale env update` to update packages in an existing conda environment based on a conda environment definition file:

```

$ adam scale -n cluster env update -f environment.yml
All nodes (x4) response:
{
  "message": "All requested packages already installed.",
  "success": true
}

```

Use `adam scale env remove` to remove a conda environment from the cluster:

```

$ adam scale -n cluster env remove -n my-env
All nodes (x4) response:
{
  "actions": {
    "PREFIX": "/opt/continuum/anaconda/envs/my-env",
    "UNLINK": [
      "mkl-11.3.3-0",
      "numpy-1.11.2-py27_0",
      "openssl-1.0.2j-0",

Using Anaconda with Cloudera CDH

There are different methods of using Anaconda Scale on a cluster with [Cloudera CDH](#):

- The freely available Anaconda parcel for Cloudera CDH.
- Custom [Anaconda parcels for Cloudera CDH](#)
- A dynamic, managed version of Anaconda on all of the nodes using Anaconda Scale

The freely available Anaconda parcel is based on Python 2.7 and includes the default conda packages that are available in the free Anaconda distribution.

Anaconda Enterprise users can also leverage Anaconda Repository to *create and distribute their own custom Anaconda parcels for Cloudera Manager*.

If you need more dynamic functionality than the Anaconda parcels offer, Anaconda Scale lets you dynamically install and manage multiple conda environments—such as Python 2, Python 3, and R environments—and packages across a cluster.

Using the Anaconda parcel

For more information about installing the Anaconda parcel on a CDH cluster using Cloudera Manager, see the [Anaconda parcel documentation](#).

Transitioning to the dynamic, managed version of Anaconda Scale

To transition from the Anaconda parcel for CDH to the dynamic, managed version of Anaconda Scale, follow the instructions below to uninstall the Anaconda parcel on a CDH cluster and then transition to a centrally managed version of Anaconda.

Uninstalling the Anaconda parcel

If the Anaconda parcel is installed on the CDH cluster, uninstall the parcel:

1. From the Cloudera Manager Admin Console, in the top navigation bar, click the Parcels indicator.
2. To the right of the Anaconda parcel listing, click the Deactivate button.
3. When prompted, click OK to deactivate the Anaconda parcel and restart Spark and related services.
4. Click the arrow to the right of the Anaconda parcel listing and select Remove From Hosts.
5. In the confirmation dialog box, confirm removal of the Anaconda parcel from the cluster nodes.

For more information about managing Cloudera parcels, see the [Cloudera documentation](#).

Transitioning to a centrally managed Anaconda installation

Once you've uninstalled the Anaconda parcel, see the [Anaconda Scale installation instructions](#) for more information about installing a centrally managed version of Anaconda.

Using Anaconda with Spark

[Apache Spark](#) is an analytics engine and parallel computation framework with Scala, Python and R interfaces. Spark can load data directly from disk, memory and other data storage technologies such as Amazon S3, Hadoop Distributed File System (HDFS), HBase, Cassandra and others.

Anaconda Scale can be used with a cluster that already has a managed Spark/Hadoop stack. Anaconda Scale can be installed alongside existing enterprise Hadoop distributions such as [Cloudera CDH](#) or [Hortonworks HDP](#) and can be used to manage Python and R conda packages and environments across a cluster.

To run a script on the head node, simply execute `python example.py` on the cluster. Alternatively, you can install Jupyter Notebook on the cluster using Anaconda Scale. See the [Installation](#) documentation for more information.

Different ways to use Spark with Anaconda

You can develop Spark scripts interactively, and you can write them as Python scripts or in a Jupyter Notebook.

You can submit a PySpark script to a Spark cluster using various methods:

- Run the script directly on the head node by executing `python example.py` on the cluster.
- Use the `spark-submit` command either in Standalone mode or with the YARN resource manager.
- Submit the script interactively in an IPython shell or Jupyter Notebook on the cluster. For information on using Anaconda Scale to install Jupyter Notebook on the cluster, see [Installation](#).

You can also use Anaconda Scale with enterprise Hadoop distributions such as Cloudera CDH or Hortonworks HDP.

Using Anaconda Scale with Spark

The topics listed below describe how to:

- Use Anaconda and Anaconda Scale with Apache Spark and PySpark
- Interact with data stored within the Hadoop Distributed File System (HDFS) on the cluster

While these tasks are independent and can be performed in any order, we recommend that you begin with [Configuring Anaconda with Spark](#).

Configuring Anaconda with Spark

You can configure Anaconda to work with Spark jobs in three ways: *with the “`spark-submit`” command*, or *with Jupyter Notebooks and Cloudera CDH*, or *with Jupyter Notebooks and Hortonworks HDP*.

After you configure Anaconda with one of those three methods, then you can *create and initialize a SparkContext*.

Configuring Anaconda with the `spark-submit` command

You can submit Spark jobs using the `PYSPARK_PYTHON` environment variable that refers to the location of the Python executable in Anaconda.

EXAMPLE:

```
PYSPARK_PYTHON=/opt/continuum/anaconda/bin/python spark-submit pyspark_script.py
```

Configuring Anaconda with Jupyter Notebooks and Cloudera CDH

Configure Jupyter Notebooks to use Anaconda Scale with Cloudera CDH using the following Python code at the top of your notebook:

```
import os
import sys
os.environ["PYSPARK_PYTHON"] = "/opt/continuum/anaconda/bin/python"
os.environ["JAVA_HOME"] = "/usr/java/jdk1.7.0_67-cloudera/jre"
os.environ["SPARK_HOME"] = "/opt/cloudera/parcels/CDH/lib/spark"
os.environ["PYLIB"] = os.environ["SPARK_HOME"] + "/python/lib"
sys.path.insert(0, os.environ["PYLIB"] + "/py4j-0.9-src.zip")
sys.path.insert(0, os.environ["PYLIB"] + "/pyspark.zip")
```

The above configuration was tested with Cloudera CDH 5.11 and Spark 1.6. Depending on the version of Cloudera CDH that you have installed, you might need to customize these paths according to the location of Java, Spark and Anaconda on your cluster.

If you've installed a custom Anaconda parcel, the path for PYSPARK_PYTHON will be /opt/cloudera/parcels/PARCEL_NAME/bin/python, where PARCEL_NAME is the name of the custom parcel you created.

Configuring Anaconda with Jupyter Notebooks and Hortonworks HDP

Configure Jupyter Notebooks to use Anaconda Scale with Hortonworks HDP using the following Python code at the top of your notebook:

```
import os
import sys
os.environ["PYSPARK_PYTHON"] = "/opt/continuum/anaconda/bin/python"
os.environ["SPARK_HOME"] = "/usr/hdp/current/spark-client"
os.environ["PYLIB"] = os.environ["SPARK_HOME"] + "/python/lib"
sys.path.insert(0, os.environ["PYLIB"] + "/py4j-0.9-src.zip")
sys.path.insert(0, os.environ["PYLIB"] + "/pyspark.zip")
```

The above configuration was tested with Hortonworks HDP 2.6, Apache Ambari 2.4 and Spark 1.6. Depending on the version of Hortonworks HDP that you have installed, you might need to customize these paths according to the location of Spark and Anaconda on your cluster.

If you've installed a custom Anaconda management pack, the path for PYSPARK_PYTHON will be /opt/continuum/PARCEL_NAME/bin/python, where PARCEL_NAME is the name of the custom parcel you created.

Creating a SparkContext

Once you have configured the appropriate environment variables, you can initialize a SparkContext—in yarn-client client mode in this example—using:

```
from pyspark import SparkConf
from pyspark import SparkContext
conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('anaconda-pyspark')
sc = SparkContext(conf=conf)
```

For more information about configuring Spark settings, see the [PySpark documentation](#).

Once you've initialized a `SparkContext`, you can start using Anaconda with Spark jobs. For examples of Spark jobs that use libraries from Anaconda, see *Using Anaconda with Spark*.

Running PySpark as a Spark standalone job

This example runs a minimal Spark script that imports PySpark, initializes a `SparkContext` and performs a distributed calculation on a Spark cluster in standalone mode.

Who is this for?

This example is for users of a Spark cluster that has been configured in standalone mode who wish to run a PySpark job.

Before you start

Download the `spark-basic.py` example script to the cluster node where you submit Spark jobs.

You need Spark running with the standalone scheduler. You can install Spark using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#). Some additional configuration might be necessary to use Spark in standalone mode.

Modifying the script

After downloading the `spark-basic.py` example script, open the file in a text editor on your cluster. Replace `HEAD_NODE_HOSTNAME` with the hostname or IP address of the Spark master as defined in your Hadoop configuration.

```
# spark-basic.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('spark://HEAD_NODE_HOSTNAME:7077')
conf.setAppName('spark-basic')
sc = SparkContext(conf=conf)

def mod(x):
    import numpy as np
    return (x, np.mod(x, 2))

rdd = sc.parallelize(range(1000)).map(mod).take(10)
print rdd
```

Examine the contents of the `spark-basic.py` example script.

The first code block contains imports from PySpark.

The second code block initializes the `SparkContext` and sets the application name.

The third code block contains the analysis code that uses the NumPy package to calculate the modulus of a range of numbers up to 1000, then returns and prints the first 10 results.

The fourth code block runs the calculation on the Spark cluster and prints the results. The code uses the NumPy library from Anaconda on each Spark worker.

NOTE: You may need to install NumPy on the cluster nodes using `adam scale -n cluster conda install numpy`.

Running the job

Run the script by submitting it to your cluster for execution using `spark-submit` or by running this command:

```
$ python spark-basic.py
```

The output from the above command shows the first 10 values returned from the `spark-basic.py` script:

```
16/05/05 22:26:53 INFO spark.SparkContext: Running Spark version 1.6.0

[...]

16/05/05 22:27:03 INFO scheduler.TaskSetManager: Starting task 0.0 in stage 0.0 (TID_
↪0, localhost, partition 0,PROCESS_LOCAL, 3242 bytes)
16/05/05 22:27:04 INFO storage.BlockManagerInfo: Added broadcast_0_piece0 in memory_
↪on localhost:46587 (size: 2.6 KB, free: 530.3 MB)

```

Troubleshooting

If something goes wrong, see [Help and support](#).

Further information

See the [Spark](#) and [PySpark](#) documentation:

Running PySpark with the YARN resource manager

This example runs a script on the Spark cluster with the YARN resource manager and returns the hostname of each node in the cluster.

Who is this for?

This example is for users of a Spark cluster who wish to run a PySpark job using the YARN resource manager.

Before you start

Download the `spark-yarn.py` example script to your cluster.

You need Spark running with the YARN resource manager. You can install Spark and YARN using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

Running the job

This code is almost the same as the code on the page [Running PySpark as a Spark standalone job](#), which describes the code in more detail.

Here is the complete script to run the Spark + YARN example in PySpark:

```
# spark-yarn.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-yarn')
sc = SparkContext(conf=conf)

def mod(x):
    import numpy as np
    return (x, np.mod(x, 2))

rdd = sc.parallelize(range(1000)).map(mod).take(10)
print rdd
```

NOTE: You may need to install NumPy on the cluster nodes using `adam scale -n cluster conda install numpy`.

Run the script on the Spark cluster with `spark-submit`. The output shows the first 10 values that were returned from the `spark-basic.py` script.

```
16/05/05 22:26:53 INFO spark.SparkContext: Running Spark version 1.6.0

[...]

16/05/05 22:27:03 INFO scheduler.TaskSetManager: Starting task 0.0 in stage 0.0 (TID_
↳0, localhost, partition 0,PROCESS_LOCAL, 3242 bytes)

```

Troubleshooting

If something goes wrong, see [Help and support](#).

Further information

See the [Spark](#) and [PySpark](#) documentation pages for more information.

Performing a word count on text data in HDFS

This example counts the number of words in text files that are stored in HDFS.

Who is this for?

This example is for users of a Spark cluster who wish to run a PySpark job—with the YARN resource manager—that reads and processes text files stored in HDFS.

Before you start

Download the `spark-wordcount.py` example script and the `download-data.py` script.

You need Spark running with the YARN resource manager and the Hadoop Distributed File System (HDFS). You can install Spark, YARN and HDFS using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

You also need valid [Amazon Web Services \(AWS\)](#) credentials.

Load HDFS data

Load the sample text data into HDFS. The following script transfers sample text data (approximately 6.4 GB) from a public Amazon S3 bucket to the HDFS data store on the cluster.

Download the `download-data.py` script to your cluster and insert your Amazon AWS credentials in the `AWS_KEY` and `AWS_SECRET` variables.

```
import subprocess

AWS_KEY = ''
AWS_SECRET = ''

s3_path = 's3n://{0}:{1}@blaze-data/enron-email'.format(AWS_KEY, AWS_SECRET)
cmd = ['hadoop', 'distcp', s3_path, 'hdfs:///tmp/enron']
subprocess.call(cmd)
```

NOTE: The `hadoop distcp` command might fail to run on smaller Amazon EC2 instance sizes due to memory limits.

Run the `download-data.py` script on the Spark cluster:

```
$ python download-data.py
```

After a few minutes, the text data is loaded into HDFS and ready for analysis.

Running the job

The following script reads the text files downloaded in the previous step and counts all of the words. Download the `spark-wordcount.py` example script to your cluster, and then replace `HEAD_NODE_IP` with the IP address of the head node.

```
# spark-wordcount.py
from pyspark import SparkConf
from pyspark import SparkContext

HDFS_MASTER = 'HEAD_NODE_IP'

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-wordcount')
conf.set('spark.executor.instances', 10)
sc = SparkContext(conf=conf)

distFile = sc.textFile('hdfs://{0}:9000/tmp/enron/*/*.txt'.format(HDFS_MASTER))

nonempty_lines = distFile.filter(lambda x: len(x) > 0)
print 'Nonempty lines', nonempty_lines.count()

words = nonempty_lines.flatMap(lambda x: x.split(' '))

wordcounts = words.map(lambda x: (x, 1)) \
    .reduceByKey(lambda x, y: x+y) \
    .map(lambda x: (x[1], x[0])).sortByKey(False)

print 'Top 100 words:'
print wordcounts.take(100)
```

Run the script on your Spark cluster using `spark-submit`. The output shows the 100 most frequently occurring words from the sample text data:

```
54.237.100.240: Using Spark's default log4j profile: org/apache/spark/log4j-defaults.
↳properties
15/06/13 04:58:42 INFO SparkContext: Running Spark version 1.4.0

```

Troubleshooting

If something goes wrong, see [Help and support](#).

Further information

See the [Spark](#) and [PySpark](#) documentation:

Distributed natural language processing

This example provides a simple PySpark job that utilizes the [NLTK library](#). NLTK is a popular Python package for natural language processing. This example shows you how to integrate third-party Python libraries with Spark. This example demonstrates the installation of Python libraries on the cluster, the usage of Spark with the YARN resource manager and execution of the PySpark job.

Who is this for?

This example is for users of a Spark cluster who wish to run a PySpark job with the YARN resource manager.

Before you start

Download the `spark-nltk.py` example script or `spark-nltk.ipynb` example notebook.

You need Spark running with the YARN resource manager. You can install Spark and YARN using an enterprise Hadoop distribution such as [Cloudera CDH](#) or [Hortonworks HDP](#).

Install NLTK

Install NLTK on all of the cluster nodes using the `adam scale` command:

```
$ adam scale -n cluster conda install nltk
```

You should see output similar to this from each node, which indicates that the package was successfully installed across the cluster:

```
All nodes (x4) response:
{
  "actions": {
    "EXTRACT": [
      "conda-env-2.5.2-py27_0",
      "conda-4.1.11-py27_0"
    ],
    "FETCH": [
      "conda-env-2.5.2-py27_0",
      "conda-4.1.11-py27_0"
    ],
    "LINK": [
      "conda-env-2.5.2-py27_0 1 None",
      "conda-4.1.11-py27_0 1 None"
    ],
    "PREFIX": "/opt/continuum/anaconda",
    "SYMLINK_CONDA": [
      "/opt/continuum/anaconda"
    ],
    "UNLINK": [
      "conda-4.1.6-py27_0",
      "conda-env-2.5.1-py27_0"
    ],
    "op_order": [
      "RM_FETCHED",
      "FETCH",
      "RM_EXTRACTED",
      "EXTRACT",
      "UNLINK",
      "LINK",
      "SYMLINK_CONDA"
    ]
  },
  "success": true
}
```

For this example, you need to download the NLTK sample data. Download the data on all cluster nodes by using the `adam cmd` command:

```
$ adam cmd 'sudo /opt/continuum/anaconda/bin/python -m nltk.downloader -d /usr/share/
↪nltk_data all'
```

The sample data is downloaded over a few minutes. After the download completes, you should see output similar to:

```
All nodes (x4) response: [nltk_data] Downloading collection 'all'
[nltk_data] |
[nltk_data] | Downloading package abc to /usr/share/nltk_data...
[nltk_data] | Unzipping corpora/abc.zip.
[nltk_data] | Downloading package alpino to /usr/share/nltk_data...
[nltk_data] | Unzipping corpora/alpino.zip.
[nltk_data] | Downloading package biocreative_ppi to
[nltk_data] | /usr/share/nltk_data...
....
[nltk_data] | Unzipping models/bllip_wsj_no_aux.zip.
[nltk_data] | Downloading package word2vec_sample to
[nltk_data] | /usr/share/nltk_data...
[nltk_data] | Unzipping models/word2vec_sample.zip.
[nltk_data] |
[nltk_data] Done downloading collection all
```

Running the job

Here is the complete script to run the Spark + NLTK example in PySpark:

```
# spark-nltk.py
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-nltk')
sc = SparkContext(conf=conf)

data = sc.textFile('file:///usr/share/nltk_data/corpora/state_union/1972-Nixon.txt')

def word_tokenize(x):
    import nltk
    return nltk.word_tokenize(x)

def pos_tag(x):
    import nltk
    return nltk.pos_tag([x])

words = data.flatMap(word_tokenize)
print words.take(10)

pos_word = words.map(pos_tag)
print pos_word.take(5)
```

Examine the above code example. First, it imports PySpark and creates a SparkContext:

```
from pyspark import SparkConf
from pyspark import SparkContext

conf = SparkConf()
conf.setMaster('yarn-client')
conf.setAppName('spark-nltk')
sc = SparkContext(conf=conf)
```

After a `SparkContext` is created, we can load some data into Spark. In this case, the data file is from one of the example documents provided by NLTK.

NOTE: You could also copy the data to HDFS and load it from Spark.

```
data = sc.textFile('file:///usr/share/nltk_data/corpora/state_union/1972-Nixon.txt')
```

Next is a function called `word_tokenize` that imports `nltk` on the Spark worker nodes and calls `nltk.word_tokenize`. The function is mapped to the text file that was read in the previous step:

```
def word_tokenize(x):
    import nltk
    return nltk.word_tokenize(x)

words = data.flatMap(word_tokenize)
```

You can confirm that the `flatMap` operation worked by returning some of the words in the dataset:

```
print words.take(10)
```

Finally, you can use NLTK's `part-of-speech` [tagger](#) to attach the part of speech to each word in the data set:

```
def pos_tag(x):
    import nltk
    return nltk.pos_tag([x])

pos_word = words.map(pos_tag)
print pos_word.take(5)
```

Run the script on the Spark cluster using the `spark-submit` script. The output shows the words that were returned from the Spark script, including the results from the `flatMap` operation and the POS-tagger:

```
Using Spark's default log4j profile: org/apache/spark/log4j-defaults.properties
15/06/13 05:14:29 INFO SparkContext: Running Spark version 1.4.0

[...]
```

```
[ 'Address',
  'on',
  'the',
  'State',

Troubleshooting

If something goes wrong, consult [Help and support](#).

Further information

See the [Spark](#) and [PySpark](#) documentation:

For more information on NLTK, see the [NLTK book](#).

Help and support

Support is included with the purchase of an Anaconda subscription. Visit the [support section of our website](#) for documentation and contact information for priority support.

Training and consulting

Training and consulting is available for Anaconda Scale. For more information, please [contact us](#).

4.4.6 NumbaPro

Note: This product is discontinued. This archived copy of the product documentation is provided for those customers who are still using it.

NumbaPro has been deprecated, and its code generation features have been moved into open-source [Numba](#). The CUDA library functions have been moved into [Accelerate](#), along with some Intel MKL functionality. High-level functions and access to additional native library implementations will be added in future releases of [Accelerate](#), and there will be no further updates to NumbaPro.

A NumbaPro compatibility layer (listed as release 0.22.0 of NumbaPro) provides access to the new [Accelerate](#) packages through the old NumbaPro package names. This avoids the need to change any existing code immediately for use with [Accelerate](#). A warning will be generated upon import of the compatibility layer, to highlight the deprecation of the NumbaPro package.

[Archived NumbaPro documentation](#) is still available.

NumbaPro

[Get started with the NumbaPro Quick Start \[pdf\]](#)

NumbaPro is an enhanced version of [Numba](#) which adds premium features and functionality that allow developers to rapidly create optimized code that integrates well with [NumPy](#).

With NumbaPro, Python developers can define NumPy [ufuncs](#) and [generalized ufuncs](#) (gufuncs) in Python, which are compiled to machine code dynamically and loaded on the fly. Additionally, NumbaPro offers developers the ability to target multicore and GPU architectures with Python code for both [ufuncs](#) and general-purpose code.

For targeting the GPU, NumbaPro can either do the work automatically, doing its best to optimize the code for the GPU architecture. Alternatively, CUDA-based API is provided for writing [CUDA](#) code specifically in Python for ultimate control of the hardware (with thread and block identities).

Getting Started

Let's start with a simple function to add together all the pairwise values in two NumPy arrays. Asking NumbaPro to compile this Python function to vectorized machine code for execution on the CPU is as simple as adding a single line of code (invoked via a decorator on the function):

Similarly, one can instead target the GPU for execution of the same Python function by modifying a single line in the above example:

```
@vectorize(['float32(float32, float32)'], target='gpu')
```

Targeting the GPU for execution introduces the potential for numerous GPU-specific optimizations so as a starting point for more complex scenarios, one can also target the GPU with NumbaPro via its *Just-In-Time* (JIT) compiler:

Features

Here's a list of highlighted features:

- Portable data-parallel programming through ufuncs and gufuncs for single core CPU, multicore CPU and GPU
- Bindings to CUDA libraries: cuRAND, cuBLAS, cuFFT
- Python CUDA programming for maximum control of hardware resources

User Guide

New users should first read the installation manual:

Installation

NumbaPro is part of the *Anaconda Accelerate* product. Please refer to the [Anaconda Accelerate Documentation](#) for instructions on downloading and installation.

Purchasing a License

Accelerate is included with [Anaconda Workgroup](#) and [Anaconda Enterprise](#) subscriptions.

To start a 30-day free trial just download and install the Anaconda Accelerate package.

If you already have [Anaconda](#) (free Python distribution) installed:

```
conda update conda
conda install accelerate
```

If you do not have Anaconda installed, you can download it [here](#).

Anaconda Accelerate can also be installed into your own (non-Anaconda) Python environment. For more information about Accelerate please contact sales@anaconda.com.

Update Instructions

With Anaconda Accelerate already installed, first update the `conda` package management tool to the latest version, then use `conda` to update the NumbaPro module. In the terminal:

```
$ conda update conda
$ conda update numbapro
```

CUDA GPUs Setup

CUDA Driver

NumbaPro does not ship the CUDA driver. It is users responsibility to ensure their systems are using the **latest driver**. Currently, users should use the driver shipped with [CUDA 5.5 SDK](#).

CUDA Support & Detection

NumbaPro GPU support currently requires [NVIDIA CUDA GPUs](#) with **compute-capability 2.0 or above**. Users should check their hardware with the following:

```
import numbapro
numbapro.check_cuda()
```

A sample output looks like:

```
-----libraries detection-----
Finding cublas
  located at /Users/.../lib/libcublas.dylib
Finding cusparse
  located at /Users/.../lib/libcusparse.dylib
Finding cufft
  located at /Users/.../lib/libcufft.dylib
Finding curand
  located at /Users/.../lib/libcurand.dylib
Finding nvvm
  located at /Users/.../lib/libnvvm.dylib
In /Users/.../lib
  finding libdevice.compute_20.bc      ok
  finding libdevice.compute_30.bc      ok
  finding libdevice.compute_35.bc      ok
-----hardware detection-----
Found 1 CUDA devices
id 0      GeForce GT 650M                [SUPPORTED]
        compute capability: 3.0
        pci device id: 0
        pci bus id: 1
Summary:
  1/1 devices are supported
```

This performs CUDA library and GPU detection. Discovered GPUs are listed with information for compute capability and whether it is supported by NumbaPro.

The message “cuda disabled by user” means that either the environment variable `NUMBA_DISABLE_CUDA` is set to 1 and must be set to 0, or the system is 32-bit. CUDA does not support 32-bit systems.

Basics:

Quick Start

Numba/NumbaPro uses decorators extensively to annotate function for compilation. This document explains the major decorators: `jit`, `autojit`, `vectorize` and `guvectorize`.

Types

Numba/NumbaPro decorators specializes generic python function to typed native function. All decorators except `autojit` requires type information to be supplied. Here is a table of common Numba type objects:

Kind	Numba Types
signed integer	<code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code>
unsigned integer	<code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code>
float-points	<code>float32</code> , <code>float64</code>
complex numbers	<code>complex64</code> , <code>complex128</code>
boolean	<code>bool_</code>
others	<code>void</code>

Compiler Target `target="..."`

All decorators, `jit`, `autojit`, `vectorize` and `guvectorize`, have a `target` keyword argument to select the code generation target. User provides a string to name the target. Numba supports only the `"cpu"` target. NumbaPro adds `"parallel"` and `"gpu"`. The `"parallel"` target is only available for `vectorize`, which will distributes the work across CPU threads. The `"gpu"` offloads the computation to a Nvidia CUDA GPU.

High-level APIs for CPU/GPU:

Universal Functions

With NumbaPro, [universal functions](#) (ufuncs) can be created by applying the `vectorize` decorator on to simple scalar functions. A ufunc can operates on scalars or NumPy arrays. When used on arrays, the ufunc apply the core scalar function to every group of elements from each arguments in an element-wise fashion. NumPy [Broadcasting](#) is applied to every argument with mismatching dimensions.

Example: Basic

Here is a simple example to perform element-wise addition:

The ufunc is compiled to operate on `float32` and `float64` arrays. It is used to compute element-wise addition of array *a* and *b* which are arrays of `numpy.float64` with 10 elements. The output

Usage

A generalization of the usage of the `vectorize` decorator is described in this section.

`vectorize` (*type_signatures*`[, target='cpu']`)
Returns a vectorizer object to be applied to python functions.

Parameters

- **type_signatures** – an iterable of type signatures, which are either function type object or a string describing the function type.
- **target** – a string for hardware target; e.g. “cpu”, “parallel”, “gpu”.

Returns a vectorizers object.

To use multithreaded version, change the target to “parallel”:

For CUDA target, use “gpu” for target:

```
<div class="highlight"><div class="highlight"><pre><span></span><span class="kn">from</span> <span class="nn">numba</span><span class="k">import</span> <span class="n">vectorize</span></pre></div></div>
```

Performance Guideline

A general guideline is to choose different targets for different data sizes and algorithms. The “cpu” target works well for small data sizes (approx. less than 1KB) and low compute intensity algorithms. It has the least amount of overhead. The “parallel” target works well for medium data sizes (approx. less than 1MB). Threading adds a small delay. The “gpu” target works well for big data sizes (approx. greater than 1MB) and high compute intensity algorithms. Transferring memory to and from the GPU adds significant overhead.

Universal Function Targets

There are several vectorizer versions available. The different options are listed below:

Target	Description
cpu	Single-threaded CPU
parallel	Multi-core CPU
stream	Optimize for CPU cache
	Note: Experimental. Computation speeds may vary.
gpu	CUDA GPU
	Note: This creates an <i>ufunc-like</i> object. See documentation for CUDA ufunc for detail.

Generalized Ufuncs**GPU Reduction**

Python CUDA Programming

CUDA Programming Introduction

NumbaPro provides multiple entry points for programmers of different levels of expertise on CUDA. For expert CUDA-C programmers, NumbaPro provides a Python dialect [<CUJit.html>](#) for low-level programming on the CUDA hardware. It provides full control over the hardware for fine tuning the performance of CUDA kernels. For new CUDA programmers, the high-level API such as the [universal functions \(ufunc\)](#) and [generalized ufuncs \(gufunc\)](#) are the easiest way to write array operations for the GPU.

A Very Brief Introduction to CUDA

A [CUDA GPU](#) contains one or more *streaming multiprocessors* (SMs). Each SM is a manycore processor that is optimized for high throughput. The *manycore* architecture is very different from the common multicore CPU architecture. Instead of having a large cache and complex logic for instruction level optimization, a manycore processor achieves high throughput by executing many threads in parallel on many simpler cores. It overcomes latency due to cache miss or long operations by using zero-cost context switching. It is common to launch a CUDA kernel with hundreds or thousands of threads to keep the GPU busy.

The CUDA programming model is similar to the SIMD vector model in modern CPUs. A CUDA SM schedules the same instruction from a *warp* of 32-threads at each issuing cycle. The advantage of CUDA is that the programmer does not need to handle the divergence of execution path in a warp, whereas a SIMD programmer would be required to properly mask and shuffle the vectors. The CUDA model decouples the data structure from the program logic.

To know more about CUDA, please refer to [NVIDIA CUDA-C Programming Guide](#).

CUDA Ufuncs and Generalized Ufuncs

This page describes the CUDA ufunc-like object.

To support the programming pattern of CUDA programs, CUDA Vectorize and GUVectorize cannot produce a conventional ufunc. Instead, a ufunc-like object is returned. This object is a close analog but not fully compatible with a regular NumPy ufunc. The CUDA ufunc adds support for passing intra-device arrays (already on the GPU device) to reduce traffic over the PCI-express bus. It also accepts a *stream* keyword for launching in asynchronous mode.

Example: Calling Device Functions

All CUDA ufunc kernels have the ability to call other CUDA device functions:

```
from numbapro import vectorize, cuda

# define a device function
@cuda.jit('float32(float32, float32, float32)', device=True, inline=True)
def cu_device_fn(x, y, z):
    return x ** y / z

# define a ufunc that calls our device function
@vectorize(['float32(float32, float32, float32)'], target='gpu')
def cu_ufunc(x, y, z):
    return cu_device_fn(x, y, z)
```

Generalized CUDA ufuncs

Generalized ufuncs may be executed on the GPU using CUDA, analogous to the CUDA ufunc functionality. This may be accomplished as follows:

```
from numbaipro import guvectorize

@guvectorize(['void(float32[:,:], float32[:,:], float32[:,:])'],
             '(m,n), (n,p)->(m,p)', target='gpu')
def matmulcore(A, B, C):
    ...
```

There are times when the gufunc kernel uses too many of a GPU's resources, which can cause the kernel launch to fail. The user can explicitly control the maximum size of the thread block by setting the `max_blocksize` attribute on the compiled gufunc object.

```
from numbaipro import guvectorize

@guvectorize(..., target='gpu')
def very_complex_kernel(A, B, C):
    ...

very_complex_kernel.max_blocksize = 32  # limits to 32 threads per block
```

Writing CUDA-Python

CUDA Libraries Host API

CUDA Device Management

CUDA Support

Note: Platforms supported: Linux, Windows and Mac OSX 32/64-bit. Only support CUDA devices with **compute capability 2.0 and above**. Please see [CUDA GPUs](#) for a list of CUDA GPUs and their compute capability.

Note: As of version 0.12.2, [Anaconda](#) is distributing a subset of CUDA toolkit 5.5 libraries. The following information is no longer necessary for most users.

NumbaPro searches in the system shared library path for the CUDA drivers and CUDA libraries (e.g. cuRAND, cuBLAS). Users can set environment variable **LD_LIBRARY_PATH** to the directory of the CUDA drivers to ensure that NumbaPro can find them. The instruction to do so is printed at the end of the CUDA SDK installation.

User can override the search path with the following environment variables:

- **NUMBAPRO_CUDA_DRIVER** path to CUDA driver shared library file
- **NUMBAPRO_NVVM** path to CUDA libNVVM shared library file
- **NUMBAPRO_LIBDEVICE** path to CUDA libNVVM libdevice directory which contains .bc files.

CUDA Python Specification (v0.2)

(This documents reflects the implementation of CUDA Python in NumbaPro 0.12. In time, we may refine the specification.)

As usage of Python on CUDA GPUs is becoming more mature, it has become necessary to define a formal specification for a dialect and its mapping to the [PTX ISA](#). There are places where the semantic of this dialect differs from the Python semantic. The change in semantic is necessary for us to generate high-performance code that is otherwise hard to achieve.

No-Python Mode (NPM)

CUDA Python is a superset of the *No-Python mode* (NPM). NPM is a statically typed subset of the Python language. It does not use the Python runtime; thus, it only supports lower level types; such as booleans, ints, floats, complex numbers and arrays. It does not support Python objects. Since we drop the support for objects entirely, many basic language constructs must be handled differently. For instance, a simple for-loop is:

```
for i in range(10):
    ...
```

where range returns an iterable. NPM restricts the language so that only `range` or `xrange` can be used.

For array support, NPM models the NumPy ndarray. An array is a structure with a pointer to the data, an array of shape and an array of strides. Valid attributes are `shape`, `strides`, `size` and `ndim`. Arrays cannot be unpacked. The only way to access array elements is through the `__getitem__` and `__setitem__` operators (e.g. `ary[i, j]`). Slicing is not supported. When indexing into an array, a N-dimension array must be provided with N indices.

Tuples are minimally supported for unpacking array `shape` and `strides` attributes and some return value of calls.

In time, we aim to enhance NPM to expand the supported subset and recognize more idiomatic Python patterns.

Summary:

- no object;
- no exception;
- for-loop only works on `range` or `xrange`;
- supported types: ints, floats, complex numbers, and arrays.

Type Inference

The type inference algorithm for CUDA Python differs from Numba as we recognize that its users require stronger typing to better predict code performance. This is a summary of the type inference rules:

- Implicit coercion for all ints and floats only.
- Variable type is assigned at definition but a variable can be redefined; thus its type can be modified at the next assignment.
- Inside a loop, the variable type remains unchanged even at redefinition. The type assigned at the preloop block (the dominator of the basic-block) is assumed. This greatly differs from Python semantic.

User can force the type of any value by using the type object defined in `numbapro` namespace:

```
from numbapro import cuda, int16, float32

@cuda.autojit
def a_cuda_kernel(arg):
    must_be_int16 = int16(123)
    must_be_float32 = float32(321)
```

Basic Arithmetic Operations

For binary operators `+` `-` `*`, the operands are coerced to the most generic type of the two before the computation. The result type is the coerced type.

For `floordiv //`, the coercion rule on operands for basic binary operators applies. But, the result type is always coerced to an integer of the same bitwidth and at least has 32-bits.

For `truediv /`, the operands are promoted to a floating point representation with bitwidth equals to the maximum of the two operands before the computation and at least has 32-bits. The result type is the coerced type.

For binary bitwise `&` `|` `^` `>>` `<<`, the operands must be of integer types and they are coerced to the most generic type of the two before the computation. The result type is the coerced type.

For complex numbers, only `+` `-` `*` are defined.

Please refer to the [CUDA-C Programming Guide: Arithmetic Instructions](#) for the precision each operation.

Intp

`intp` is used to represent the integer whose width equals the address width.

Array Operations

Array attributes are read-only:

- `shape` contains the number of elements for each dimension. It can be indexed or unpacked like a tuple. It is a tuple of `intp`.
- `strides` contains the number of bytes skip to move forward to the next element for a given dimension. It can be indexed or unpacked like a tuple. It is a tuple of `intp`.
- `size` contains the number of elements in the array but may not be correspond to the actual size of the data buffer since strides can be zero or negative. It is an `intp`.
- `ndim` contains the number of dimension in the array. It is an `intp`.

`__getitem__` returns the element at the given index. Slicing or fancy indexing are not supported. The result type is always the same as the element type of the array.

`__setitem__` stores a value into the array at an index. The value is coerced if necessary.

CUDA Intrinsics

All intrinsics are defined under the `numbapro.cuda` namespace.

Thread ID intrinsics:

- `cuda.threadIdx.x`, `cuda.threadIdx.y`, `cuda.threadIdx.z` are the X, Y and Z IDs of the thread.

- `cuda.blockIdx.x`, `cuda.blockIdx.y` are the X and Y ID of the block.
- `cuda.blockDim.x`, `cuda.blockDim.y`, `cuda.blockDim.z` are the X, Y and Z width of the thread block.
- `cuda.gridDim.x`, `cuda.gridDim.y` are the X and Y width of the grid.

Barrier intrinsics:

- `cuda.syncthreads()` equivalent to `__syncthreads()` in CUDA-C. It is a thread block level barrier.

Shared memory intrinsics

- `cuda.shared.array(shape, dtype)` constructs a statically allocated array in the shared memory of kernel. `dtype` argument must be a type object defined in the `NumbaPro` namespace. It must be declared in the entry block of the kernel.

Math

Python Dialect for CUDA translates math functions defined in the `math` module of the Python standard library. All the functions use the semantic of the CUDA-C definition. Please refer to the [CUDA-C Programming Guide: Math Function](#).

Supported functions:

```
math.acos
math.asin
math.atan
math.arctan
math.acosh
math.asinh
math.atanh
math.cos
math.sin
math.tan
math.cosh
math.sinh
math.tanh
math.atan2
math.exp
math.expm1           # not available in Python 2.6
math.fabs
math.log
math.log10
math.log1p
math.sqrt
math.pow
math.ceil
math.floor
math.copysign
math.fmod
math.isnan
math.isinf
```

Fast Math

coming soon in the next release...

Learn by Examples

The developer team maintains a public [GitHub repository of examples](#). Many examples are designed to show off the potential performance gain by using GPUs.

Requirements

Base:

- Python 2.6, 2.7, 3.3, 3.4
- LLVM 3.3

For CUDA GPU features:

- Latest NVIDIA CUDA driver
- CUDA Toolkit 5.5 or above
- At least one CUDA GPU with compute capability 2.0 or above

Python modules:

- llvmpy 0.12.7 or above
- numba 0.14.0 or above

Release Notes

Version (0.21.0)

NumbaPro will be deprecated with most code generation features moved into the opensource Numba and the CUDA bindings moved into a new commercial package called “Accelerate”. The new package will feature more high-level API functions from the CUDA libraries as well as MKL.

The next release of NumbaPro will provide aliases to the features that are moved to Numba and Accelerate. There will not be any new feature added to NumbaPro. In the future, there may be bug fix releases for maintaining the aliases to the moved features.

Changes:

- Depends on numba 0.21.0
- Fix auto thread-per-block tuning support for CUDA CC 3.7 devices
- `Blas.dotu` is deprecated. A warning is generated when it is used. `Blas.dot` is an alias to it and is preferred.

Version (0.20.0)

This release depends on numba 0.20, which has upgraded to CUDA 7 for GPU support. CUDA 7 has deprecated the support for all 32-bit platforms. The oldest supported Windows version is Windows 7.0. This does not affect CPU features.

Version (0.19.0)

- Depends on numba 0.19
- Fixes issue with GPU ufunc broadcasting
- Improves GPU ufunc implementation

Version (0.18.0)

- Depends on numba 0.18.1
- **Improve CUDA gufunc implementation**
 - Simplified code generation
 - Smarter blocksize selection

Version (0.17.1)

- Depends on numba 0.17.0
- Warns about incompatible numba version at import time
- Fixes some CUDA library APIs on windows

Version (0.17.0)

- Depends on numba 0.16.0
- Replaces llvmpy with llvmlite, which also upgrades to llvm3.5
- Update occupancy autotuner for CC 5.0 and CC 5.2 devices
- Fix handling of empty array in GPU reduction
- Fix occupancy autotuner that may pick invalid blocksize

Version (0.16.0)

- Add *numbapro.cuda.reduce* for autogeneration of CUDA reduce kernels and driver.
- Fix device to host auto transfer logic in some ufunc function.
- Upgrades to Numba 0.15

Version (0.15.0)

- **Add *numbapro.cudalib.sorting*:**
 - Added GPU radixsort and radixselect using implementation from <http://nvlabs.github.io/cub>
 - Added GPU segmented sort from <http://nvlabs.github.io/moderngpu>
- Fix GPU *print()* when there are multiple arguments

Version (0.14.3)

- CUDA driver is initialized lazily
- Improved stability of CUDA ufunc machinery
- Improved stability of parallel ufunc

Version (0.14.2)

- Unify numba.cuda and numbapro.cuda backend
- Enable Python 3 support
- Fixes workqueue module import for embedded python usecase

Version (0.14.1)

Fixes:

- UnboundReferenceError due to mishandling of incompatible driver (pre CUDA5.5 driver). The fix relaxes the driver requirement by allowing some features to fail on use.
- numbapro.cuda.* symbols are still exported when CUDA is not available. They would raise exception on use.

Version (0.14.0)

Features:

- Add cuSparse API
- Improve CUDA driver and resource management
- Some of CUDA-python language feature is now opensourced as numba.cuda

Fixes:

- New CUDA driver system prevents freezing OSX on kernel launch error

Version (0.13.2)

- Fix problem with numpy 18 array scalar contiguousness
- Fix CUDA target auto initialization on *import numbapro*
- Fix an access violation error on Windows 8 due to mishandling by LLVM.
- Add non-public API for profiler control.

Version (0.13.1)

- Guard error due to mishandling of interleaved memory buffer (#60)
- Update to use Numba 0.12.1
- Fix powi bug

Version (0.13)

- Add print statement for strings and scalar numeric types for debugging on GPU
- Add constant and local memory array allocation on GPU
- Add debug mode for GPU
- Allow raising exception classes on GPU
- Update CUDA toolkit libraries
- Fix boolean mapping

Version (0.12.7)

- Fix major bug that mistreats py2 division as inplace floor-division for real numbers.
- Fix using of array as argument of a CUDA device function.
- Delay initialization the CUDA subsystem upon first import of the cuda package.
- Add docstrings.

Version (0.12.6)

- Fix major bug that mistreats py2 division as floor-division for real numbers.

Version (0.12.5)

- Update to Numba 0.10.2
- Update to LLVM 3.3
- Various bug fixes

Version (0.12.4)

- Update to Numba 0.10.0
- Minor bug fixes

Version (0.12.3)

- Accept older driver by deferring driver error to first use of specific API
- Report incompatible GPU at context creation
- Improve device information reporting
- Autotuning base on compiler info and occupancy calculator
- Add basic support for ravel and reshape

Version (0.12.2)

- Distribute CUDA toolkit in Anaconda
- Better error message
- Fix gufunc signature parsing to accept trailing comma.
- Fix CUDA driver log info bug
- Support JIT linking

Version (0.12.1)

- Fix libNVVM search path (now accept directory path)
- Fix sign-extension error in forloop precondition
- Fix support for true-division

Version (0.12.0)

- Use CUDA 5.5rc
- Expand math support through CUDA NVVM libdevice
- Rewritten nopython mode for CUDA-Python
- Removed experimental CU API
- Removed minivectorize

Version (0.11.0)

- Add cuBlas binding
- Improve CUDA ndarray and memory management
- Add CUDA mapped host memory
- Add CUDA event

Version (0.10.1)

- Fix CU memory leak
- Fix CU hanging on some GPU
- Improve error message for unsupported GPU devices
- Add cuFFT

Version (0.10)

- Added Compute Unit (CU) API
- Added cuRAND binding
- Added CUDA device array
- Various improvements to CUDA support

Version (0.9)

- Improve CUDA driver discovery.

Version 0.8

- Update for SSA types inference in Numba
- Allow user to select CUDA device
- Add support for pinned and mapped CUDA memory
- Improvement on small memory allocation in CUDA
- Default to use libNVVM from Anaconda
- Bug fixes

Version 0.7

- Prange: parallel for-range
- Array slicing
- Refactor CUDA dispatch mechanisms
- Migrate to NVVM instead of PTX for CUDA codegen

Version 0.6 and earlier

- Array expressions
- Fast ufuncs and generalized-ufunc (gufunc) with single-core, multi-core and CUDA
- CUDA JIT.

END USER LICENSE AGREEMENT

NumbaPro (“the Software Product”) and accompanying documentation is licensed and not sold. The Software Product is protected by copyright laws and treaties, as well as laws and treaties related to other forms of intellectual property.

Continuum Analytics, Inc. (dba Anaconda, Inc.) or its subsidiaries, affiliates, and suppliers (collectively “Continuum”) own intellectual property rights in the Software Product. The Licensee’s (“you” or “your”) license to download, use, copy, or change the Software Product is subject to these rights and to all the terms and conditions of this End User License Agreement (“Agreement”).

Acceptance

YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS AGREEMENT BY SELECTING THE “ACCEPT” OPTION AND DOWNLOADING THE SOFTWARE PRODUCT OR BY INSTALLING, USING, OR COPYING THE SOFTWARE PRODUCT. YOU MUST AGREE TO ALL OF THE TERMS OF THIS AGREEMENT BEFORE YOU WILL BE ALLOWED TO DOWNLOAD THE SOFTWARE PRODUCT. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, YOU MUST SELECT “DECLINE” AND YOU MUST NOT INSTALL, USE, OR COPY THE SOFTWARE PRODUCT.

Trial Period

You have the right to use NumbaPro on a single computer or group of computers for 30 days with no license. After 30 days you must purchase an appropriate license to use the software on one or more machines or stop using the software and remove it from all of your machines on which you installed the software.

License Grant

This Agreement entitles you to install and use one copy of the Software Product on as many machines as you will personally use. The Software Product is licensed to a particular user. Only the user to whom the software is licensed may use the software. You must obtain a license for as many users as you wish to use the software. In addition, you may make archival copies of the Software Product Installer.

Restrictions on Transfer

Without first obtaining the express written consent of Continuum, you may not assign your rights and obligations under this Agreement, or redistribute, encumber, sell, rent, lease, sublicense, or otherwise transfer your rights to the Software Product.

Restrictions on Use

You may not use, copy, or install the Software Product on any system where more than one user will be able to use the software unless you have purchased a license for each user of the system. You may not decompile, “reverse-engineer”, disassemble, or otherwise attempt to derive the source code for the Software Product.

Restrictions on Alteration

You may not modify the Software Product or create any derivative work of the Software Product or its accompanying documentation. Derivative works include but are not limited to translations. You may not alter any files or libraries in any portion of the Software Product.

Restrictions on Copying

You may not copy any part of the Software Product except to the extent that licensed use inherently demands the creation of a temporary copy stored in computer memory and not permanently affixed on storage medium. You may make archival copies of the Software Product installer.

Limited Software Product Warranty

For a period of 60 days from the date of shipment or from the date that you download the Software Product, as applicable, Continuum warrants that when properly installed and used under normal conditions, the Software Product will perform substantially as advertised.

Disclaimer of Warranties and Limitation of Liability

UNLESS OTHERWISE EXPLICITLY AGREED TO IN WRITING BY CONTINUUM, CONTINUUM MAKES NO OTHER WARRANTIES, EXPRESS OR IMPLIED, IN FACT OR IN LAW, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE OTHER THAN AS SET FORTH IN THIS AGREEMENT OR IN THE LIMITED WARRANTY DOCUMENTS PROVIDED WITH THE SOFTWARE PRODUCT.

Continuum makes no warranty that the Software Product will meet your requirements or operate under your specific conditions of use. Continuum makes no warranty that operation of the Software Product will be secure, error free, or free from interruption. YOU MUST DETERMINE WHETHER THE SOFTWARE PRODUCT SUFFICIENTLY MEETS YOUR REQUIREMENTS FOR SECURITY AND UNINTERRUPTABILITY. YOU BEAR SOLE RESPONSIBILITY AND ALL LIABILITY FOR ANY LOSS INCURRED DUE TO FAILURE OF THE SOFTWARE PRODUCT TO MEET YOUR REQUIREMENTS. CONTINUUM WILL NOT, UNDER ANY CIRCUMSTANCES, BE RESPONSIBLE OR LIABLE FOR THE LOSS OF DATA ON ANY COMPUTER OR INFORMATION STORAGE DEVICE. UNDER NO CIRCUMSTANCES SHALL CONTINUUM, ITS DIRECTORS, OFFICERS, EMPLOYEES OR AGENTS BE LIABLE TO YOU OR ANY OTHER PARTY FOR INDIRECT, CONSEQUENTIAL, SPECIAL, INCIDENTAL, PUNITIVE, OR EXEMPLARY DAMAGES OF ANY KIND (INCLUDING LOST REVENUES OR PROFITS OR LOSS OF BUSINESS) RESULTING FROM THIS AGREEMENT, OR FROM THE FURNISHING, PERFORMANCE, INSTALLATION, OR USE OF THE SOFTWARE PRODUCT, WHETHER DUE TO A BREACH OF CONTRACT, BREACH OF WARRANTY, OR THE NEGLIGENCE OF CONTINUUM OR ANY OTHER PARTY, EVEN IF CONTINUUM IS ADVISED BEFOREHAND OF THE POSSIBILITY OF SUCH DAMAGES. TO THE EXTENT THAT THE APPLICABLE JURISDICTION LIMITS CONTINUUM'S ABILITY TO DISCLAIM ANY IMPLIED WARRANTIES, THIS DISCLAIMER SHALL BE EFFECTIVE TO THE MAXIMUM EXTENT PERMITTED.

Limitation of Remedies and Damages

Your remedy for a breach of this Agreement or of any warranty included in this Agreement is the correction or replacement of the Software Product. Selection of whether to correct or replace shall be solely at the discretion of Continuum. Continuum reserves the right to substitute a functionally equivalent copy of the Software Product as a replacement. If Continuum is unable to provide a replacement or substitute Software Product or corrections to the Software Product, your sole alternate remedy shall be a refund of the purchase price for the Software Product exclusive of any costs for shipping and handling. Any claim must be made within the applicable warranty period. All warranties cover only defects arising under normal use and do not include malfunctions or failure resulting from misuse, abuse, neglect, alteration, problems with electrical power, acts of nature, unusual temperatures or humidity, improper installation, or damage determined by Continuum to have been caused by you. All limited warranties on the Software Product are granted only to you and are non-transferable. You agree to indemnify and hold Continuum

harmless from all claims, judgments, liabilities, expenses, or costs arising from your breach of this Agreement and/or acts or omissions.

Governing Law, Jurisdiction and Costs

This Agreement is governed by the laws of Texas, without regard to Texas's conflict or choice of law provisions.

Severability

If any provision of this Agreement shall be held to be invalid or unenforceable, the remainder of this Agreement shall remain in full force and effect. To the extent any express or implied restrictions are not permitted by applicable laws, these express or implied restrictions shall remain in force and effect to the maximum extent permitted by such applicable laws.

Third Party Dependencies

The following sections enumerate NumbaPro thirdparty dependencies and their license information.

CUDA Toolkit Redistributable Libraries

The `cuda-toolkit` conda package contains redistributable binaries from the CUDA toolkit. See CUDA toolkit EULA at <http://docs.nvidia.com/cuda/eula/index.html>

CUB

The `nbpro_radixsort.so` library (shipped in `numbapro_cudalib` conda package) uses CUB (<http://nvlabs.github.io/cub>) which has the following license:

```
Copyright (c) 2011, Duane Merrill. All rights reserved.
Copyright (c) 2011-2014, NVIDIA CORPORATION. All rights reserved.
Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions are met:
    Redistributions of source code must retain the above copyright
        notice, this list of conditions and the following disclaimer.
    Redistributions in binary form must reproduce the above copyright
        notice, this list of conditions and the following disclaimer in the
        documentation and/or other materials provided with the distribution.
    Neither the name of the NVIDIA CORPORATION nor the
        names of its contributors may be used to endorse or promote products
        derived from this software without specific prior written permission.
THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND
ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED
WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE
DISCLAIMED. IN NO EVENT SHALL NVIDIA CORPORATION BE LIABLE FOR ANY
DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES
(INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES;
LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND
ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT
(INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS
SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
```

ModernGPU

The `nbpro_segsort.so` library (shipped in `numbapro_cudalib` conda package) uses ModernGPU (<http://nvlabs.github.io/moderngpu>) which has the following license:

```
Copyright (c) 2013, NVIDIA CORPORATION. All rights reserved.

Redistribution and use in source and binary forms, with or without
modification, are permitted provided that the following conditions are met:
  * Redistributions of source code must retain the above copyright

SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
```

4.4.7 MKL Optimizations

Developed specifically for science, engineering, and financial computations, Intel™ Math Kernel Library (MKL) is a set of threaded and vectorized math routines that work to accelerate various math functions and applications. Anaconda has packaged MKL-powered binary versions of some of the most popular numerical/scientific Python libraries into MKL Optimizations for improved performance.

MKL Optimizations includes:

- Speed-boosted NumPy, SciPy, scikit-learn, and NumExpr
- The packaging of MKL with redistributable binaries in Anaconda for easy access to the MKL runtime library.
- Python bindings to the low level MKL service functions, which allow for the modification of the number of threads being used during runtime.

Included Packages

Packages upgraded to use MKL

- NumPy
- NumExpr
- SciPy
- Scikit-Learn

mkl-service

This package exposes a few functions which are declared in `mkl_service.h`. The main purpose of the package is to allow the user to change the number of CPU's MKL is using at runtime.

Example:

In this small example, we first query how many CPU are being used, and then change this number.

```
>>> import mkl
>>> mkl.get_max_threads()
2
>>> mkl.set_num_threads(1)
>>> mkl.get_max_threads()
1
```

Reference

mkl service functions:

mkl.get_cpu_clocks() -> int Return the CPU clocks as an integer.

mkl.get_cpu_frequency() -> float Return CPU frequency in GHz as a float.

mkl.get_max_threads() -> int Return the number of threads Intel MKL is targeting for parallelism.

mkl.get_version_string() -> str Return the MKL library version information as a string.

mkl.mem_stat(n) -> int Returns an amount of memory, allocated by the MKL Memory Allocator.

mkl.set_num_threads(n) Set the number of threads MKL should use. This is only a hint, and no guaranteed is made this number of threads will actually be used. This function takes precedence over the environment variable `MKL_NUM_THREADS`.

Installation

In Anaconda versions 2.5 and later, MKL is [freely available by default in Anaconda](#).

If you already have the free [Anaconda](#) Python distribution installed, get MKL by upgrading to the latest version:

```
conda update conda
conda update anaconda
```

If you do not have Anaconda installed, you can download it [here](#).

Existing MKL licenses can be viewed and removed with the graphical Anaconda Navigator license manager or manually with your operating system.

Configuration

Anaconda now also includes a small utility package called `mkl-service` which provides a Python interface to some useful MKL functions that are declared in `mkl_service.h`, such as setting the number of threads to use.

Uninstalling MKL

MKL takes roughly 100MB and some use cases do not need it, so users can opt out of MKL and instead use [OpenBLAS](#) for Linux or the native Accelerate Framework for MacOSX. To opt out, run `conda install nomkl` and then use `conda install` to install packages that would normally include MKL or depend on packages that include MKL, such as `scipy`, `numpy`, and `pandas`. Conda will install the non-MKL versions of these packages together with their dependencies. If you are using OS X or Linux, have already installed these packages or already installed all of Anaconda, and wish to switch away from MKL, use the command `conda install nomkl numpy scipy scikit-learn numexpr` followed by `conda remove mkl mkl-service`.

Updating

If you already have the free Anaconda Python distribution installed and wish to update MKL:

```
conda update conda
conda update mkl
```

Dismissing MKL Trial warnings

Because past versions of Anaconda did not include MKL linked binaries by default, some users who have used `conda update --all` may see an MKL Trial warning or a license expiration error, even though MKL linked packages are now free and installed by default. A license expiration error message may read, “You cannot run MKL without a license any longer.”

To resolve this, set your installation to use the mkl-linked libraries that do not require a license:

```
conda remove mkl-rt
conda install -f mkl
```

Then run `conda install` with the specific packages you choose:

```
conda install numpy scipy scikit-learn numexpr
```

or with all of Anaconda:

```
conda install anaconda
```

Resolving MKL shared library “permission denied” errors

On Linux platforms that have SELinux enabled, you may encounter security errors like the following:

```
error while loading shared libraries: <libmkl_intel.so>: cannot restore segment prot_
↪after reloc: Permission denied
```

This is because MKL requires text relocation permissions, which SELinux denies by default. This prevents MKL from being loaded by Numpy, preventing Numpy from being imported.

There are two known solutions to this issue:

1. Does not require root privileges. Replace MKL with OpenBLAS by issuing the command:

```
conda install nomkl numpy scipy scikit-learn numexpr
```

You may revert back to the MKL default versions at any time by using:

```
conda remove nomkl
conda install mkl
```

2. Requires root privileges. Temporarily disable SELinux enforcement. From a root-privileged terminal enter:

```
/usr/sbin/setenforce 0
```

NOTE: If you prefer to make this change permanent, in the file `/etc/selinux/config` change “enforcing” to “disabled” and then reboot.

License Agreement

The MKL Optimizations are included in the free Anaconda python distribution, and have been made available by the terms of the *End User License Agreement - Anaconda® Individual Edition*.

Past versions of MKL Optimizations were not freely available in Anaconda, and have been made available separately by the terms of the *MKL Optimizations End User License Agreement*.

MKL Optimizations End User License Agreement

MKL Optimizations (“the Software Product” or “MKL Optimizations”) and accompanying documentation is licensed and not sold. The Software Product is protected by copyright laws and treaties, as well as laws and treaties related to other forms of intellectual property. Continuum Analytics, Inc. (dba Anaconda, Inc.) or its subsidiaries, affiliates, and suppliers (collectively “Continuum”) own intellectual property rights in the Software Product. The Licensee’s (“you” or “your”) license to download, use, copy, or change the Software Product is subject to these rights and to all the terms and conditions of this End User License Agreement (“Agreement”).

Acceptance

YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS AGREEMENT BY SELECTING THE “ACCEPT” OPTION AND DOWNLOADING THE SOFTWARE PRODUCT OR BY INSTALLING, USING, OR COPYING THE SOFTWARE PRODUCT. YOU MUST AGREE TO ALL OF THE TERMS OF THIS AGREEMENT BEFORE YOU WILL BE ALLOWED TO DOWNLOAD THE SOFTWARE PRODUCT. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, YOU MUST SELECT “DECLINE” AND YOU MUST NOT INSTALL, USE, OR COPY THE SOFTWARE PRODUCT.

Other Vendor Tools

In addition to Continuum’s proprietary software, the Software product may contain other software packages from other sources (“Other Vendor Tools”). These are available on an “as is” basis and subject to their individual license agreements. These licenses are available either in the package distributed with the Software Product or via request to info@anaconda.com. Any binary packages of Other Vendor Tools you obtain via MKL Optimizations are subject to their individual licenses as well as the terms of this EULA. Continuum reserves the right to change which Other Vendor Tools are provided in MKL Optimizations.

Trial Period

You have the right to use MKL Optimizations on a single computer or group of computers for 30 days with no license. After 30 days you must purchase an appropriate license to use the software on one or more machines or stop using the software and remove it from all of your machines on which you installed the software.

License Grant

This Agreement entitles you to install and use one copy of the Software Product on as many machines as you will personally use. The Software Product is licensed to a particular user. Only the user to whom the software is licensed may use the software. You must obtain a license for as many users as you wish to use the software. In addition, you may make archival copies of the Software Product Installer.

Right to Updates

This license entitles you to updates to the Software Product for one year from the time of payment. The Software Product will continue to function and you may continue to use The Software Product and any updates you have received for as long as you would like however you will no longer be able to receive updates from Continuum unless this License is renewed. Please contact sales@anaconda.com with any questions or concerns.

Restrictions on Transfer

Without first obtaining the express written consent of Continuum, you may not assign your rights and obligations under this Agreement, or redistribute, encumber, sell, rent, lease, sublicense, or otherwise transfer your rights to the Software Product.

Restrictions on Use

You may not use, copy, or install the Software Product on any system where more than one user will be able to use the software unless you have purchased a license for each user of the system. You may not decompile, “reverse-engineer”, disassemble, or otherwise attempt to derive the source code for the Software Product.

Restrictions on Alteration

You may not modify the Software Product or create any derivative work of the Software Product or its accompanying documentation. Derivative works include but are not limited to translations. You may not alter any files or libraries in any portion of the Software Product.

Restrictions on Copying

You may not copy any part of the Software Product except to the extent that licensed use inherently demands the creation of a temporary copy stored in computer memory and not permanently affixed on storage medium. You may make archival copies of the Software Product installer.

Limited Software Product Warranty

For a period of 60 days from the date of shipment or from the date that you download the Software Product, as applicable, Continuum warrants that when properly installed and used under normal conditions, the Software Product will perform substantially as advertised.

Disclaimer of Warranties and Limitation of Liability

UNLESS OTHERWISE EXPLICITLY AGREED TO IN WRITING BY CONTINUUM, CONTINUUM MAKES NO OTHER WARRANTIES, EXPRESS OR IMPLIED, IN FACT OR IN LAW, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE OTHER THAN AS SET FORTH IN THIS AGREEMENT OR IN THE LIMITED WARRANTY DOCUMENTS PROVIDED WITH THE SOFTWARE PRODUCT.

Continuum makes no warranty that the Software Product will meet your requirements or operate under your specific conditions of use. Continuum makes no warranty that operation of the Software Product will be secure, error free, or free from interruption. YOU MUST DETERMINE WHETHER THE SOFTWARE PRODUCT SUFFICIENTLY MEETS YOUR REQUIREMENTS FOR SECURITY AND UNINTERRUPTABILITY. YOU BEAR SOLE RESPONSIBILITY AND ALL LIABILITY FOR ANY LOSS INCURRED DUE TO FAILURE OF THE SOFTWARE PRODUCT TO MEET YOUR REQUIREMENTS. CONTINUUM WILL NOT, UNDER ANY CIRCUMSTANCES, BE RESPONSIBLE OR LIABLE FOR THE LOSS OF DATA ON ANY COMPUTER OR INFORMATION STORAGE DEVICE. UNDER NO CIRCUMSTANCES SHALL CONTINUUM, ITS DIRECTORS, OFFICERS, EMPLOYEES OR AGENTS BE LIABLE TO YOU OR ANY OTHER PARTY FOR INDIRECT, CONSEQUENTIAL, SPECIAL, INCIDENTAL, PUNITIVE, OR EXEMPLARY DAMAGES OF ANY KIND (INCLUDING LOST REVENUES OR PROFITS OR LOSS OF BUSINESS) RESULTING FROM THIS AGREEMENT, OR FROM THE FURNISHING, PERFORMANCE, INSTALLATION, OR USE OF THE SOFTWARE PRODUCT, WHETHER DUE TO A BREACH OF CONTRACT, BREACH OF WARRANTY, OR THE NEGLIGENCE OF CONTINUUM OR ANY OTHER PARTY, EVEN IF CONTINUUM IS ADVISED BEFOREHAND OF THE POSSIBILITY OF SUCH DAMAGES. TO THE EXTENT THAT THE APPLICABLE JURISDICTION LIMITS CONTINUUM'S ABILITY TO DISCLAIM ANY IMPLIED WARRANTIES, THIS DISCLAIMER SHALL BE EFFECTIVE TO THE MAXIMUM EXTENT PERMITTED.

Limitation of Remedies and Damages

Your remedy for a breach of this Agreement or of any warranty included in this Agreement is the correction or replacement of the Software Product. Selection of whether to correct or replace shall be solely at the discretion of Continuum. Continuum reserves the right to substitute a functionally equivalent copy of the Software Product as a replacement. If Continuum is unable to provide a replacement or substitute Software Product or corrections to the Software Product, your sole alternate remedy shall be a refund of the purchase price for the Software Product exclusive of any costs for shipping and handling. Any claim must be made within the applicable warranty period. All warranties cover only defects arising under normal use and do not include malfunctions or failure resulting from misuse, abuse, neglect, alteration, problems with electrical power, acts of nature, unusual temperatures or humidity, improper installation, or damage determined by Continuum to have been caused by you. All limited warranties on the Software Product are granted only to you and are non-transferable. You agree to indemnify and hold Continuum harmless from all claims, judgments, liabilities, expenses, or costs arising from your breach of this Agreement and/or acts or omissions.

Governing Law, Jurisdiction and Costs

This Agreement is governed by the laws of Texas, without regard to Texas's conflict or choice of law provisions.

Export Regulations

Any use or distribution of MKL Optimizations is made under conditions that the user and/or distributor is in full compliance with all export and other governing laws of the United States of America, including full and ongoing compliance with the Export Administration Regulations (EAR) of the United States Department of Commerce. See www.commerce.gov/ and <http://www.bis.doc.gov/index.php/regulations/export-administration-regulations-ear>. Use

or distribution of Continuum software products to any persons, entities or countries currently under US sanctions is strictly prohibited. MKL Optimizations is classified with an ECCN of 5D992 with no license required for export to non-embargoed countries.

The United States currently has embargoes against Cuba, Iran, North Korea, Sudan and Syria. The exportation, re-exportation, sale or supply, directly or indirectly, from the United States, or by a U.S. person wherever located, of any Continuum software to any of these countries is strictly prohibited without prior authorization by the United States Government. By accepting this Agreement, you represent to Continuum that you will comply with all applicable export regulations for MKL Optimizations.

Severability

If any provision of this Agreement shall be held to be invalid or unenforceable, the remainder of this Agreement shall remain in full force and effect. To the extent any express or implied restrictions are not permitted by applicable laws, these express or implied restrictions shall remain in force and effect to the maximum extent permitted by such applicable laws.

4.4.8 IOPro

IOPro loads NumPy arrays (and Pandas DataFrames) directly from files, SQL databases, and NoSQL stores—including ones with millions of rows—without creating millions of temporary, intermediate Python objects, or requiring expensive array resizing operations.

IOPro provides a drop-in replacement for the NumPy functions `loadtxt()` and `genfromtxt()`, but dramatically improves performance and reduces memory overhead.

The current (and final) version of IOPro 1.9.1 was released on March 1, 2017.

The open source successors to IOPro

All of the code in IOPro was released in 2017 under a BSD open source license. As part of that release, the code was refactored into its several component libraries, and version numbers of each were set to 2.0.0 to indicate they supersede the code under the IOPro name.

The several libraries are available on GitHub at:

- [TextAdapter](#) (CSV, JSON, etc)
- [DBAdapter](#) (SQL derivatives)
- [PostgresAdapter](#) (PostgreSQL)
- [AccumuloAdapter](#) (Apache Accumulo)
- [MongoAdapter](#) (MongoDB)

These various packages may be available as conda packages (using lowercase versions of their names) in the conda-forge channel. Maintenance, improvements, and packaging will be a community-led project.

How to get IOPro

To get IOPro just download and install the IOPro package.

If you already have [Anaconda](#) (free Python platform) or [Miniconda](#) installed:

```
conda update conda
conda install -c pkgs/pro iopro=1.9.1
```

If you do not have Anaconda installed, you can [download it](#).

Requirements

- Python 2.7 or 3.4+
- NumPy 1.10+

Optional Python modules:

- Boto (for S3 support)
- Pandas (to use DataFrames)

What's new in version 1.9?

The documentation has been substantially updated for version 1.9.0. Numba has been removed and the code has been cleaned up, but no other features were added or removed. Some refactoring was done that didn't change functionality. We recommend that users not use older versions. See [Release notes](#) for additional detail.

Getting started

Some of the basic usage patterns look like these. Create TextAdapter object for data source:

```
>>> import iopro
>>> adapter = iopro.text_adapter('data.csv', parser='csv')
```

Define field dtypes (example: set field 0 to unsigned int and field 4 to float):

```
>>> adapter.set_field_types({0: 'u4', 4: 'f4'})
```

Parse text and store records in NumPy array using slicing notation:

```
>>> # read all records
>>> array = adapter[:]

>>> # read first ten records
>>> array = adapter[0:10]

>>> # read last record
>>> array = adapter[-1]

>>> # read every other record
>>> array = adapter[::2]
```

User guide

Installation

If you do not already have Anaconda installed, please download it via the [downloads page](#) and install it.

IOPro is included with [Anaconda Workgroup](#) and [Anaconda Enterprise](#) subscriptions.

To start a 30-day free trial just download and install the IOPro package.

If you already have [Anaconda](#) (free Python platform) or [Miniconda](#) <<http://conda.io/miniconda.html>> installed:

```
conda update conda
conda install iopro
```

If you do not have Anaconda installed, you can [download it](#).

For more information about IOPro please contact sales@anaconda.com.

IOPro Update Instructions

If you have Anaconda (free Python platform) installed, first update the conda package management tool to the latest version, then use conda to update the IOPro product installation:

```
conda update conda
conda update iopro
```

Uninstall

To uninstall using conda:

```
conda remove iopro
```

Installing license

The IOPro license can be installed with the graphical Anaconda Navigator license manager or manually with your operating system. In your organization this may be handled by your site administrator or IT department.

TextAdapter First Steps

Basic Usage

IOPro works by attaching to a data source, such as a local CSV file. Before we get started, let's create a sample CSV file to work with:

```
from random import random, randint, shuffle
import string

NUMROWS = 10
with open('data/table.csv', 'w') as data:
    # Header
    for n in range(1, 5):
        print("f%d" % n, end=", ", file=data)
    print("comment", file=data)

    # Body
    letters = list(string.ascii_letters)
    for n in range(NUMROWS):
```

(continues on next page)

(continued from previous page)

```

shuffle(letters)
s = "".join(letters[:randint(5,20)])
vals = (n, randint(1000,2000), random(), random()*100, s)
print("%d,%d,%f,%f,%s" % vals, file=data)

```

Let's read in the local CSV file created here. Because this small file easily fits in memory it would work to use the csv or pandas modules, but we will demonstrate the interfaces and capabilities that will apply to much larger data.

```

>>> import iopro
>>> adapter = iopro.text_adapter('data/table.csv', parser='csv')
>>> adapter.get_field_names()
['f1', 'f2', 'f3', 'f4', 'comment']

```

We can specify the data types for values in the columns of the CSV file being read; but first we look at the ability of IOPro's TextAdapter to auto-discover the data types used.

We can ask IOPro's TextAdapter to parse text and return records in NumPy arrays from selected portions of the CSV file using slicing notation:

```

>>> # the inferred datatypes
>>> array = adapter[:]
>>> array.dtype
dtype([('f1', '<u8'), ('f2', '<u8'), ('f3', '<f8'), ('f4', '<f8'),
      ('comment', 'O')])

```

Let's define field dtypes (example: set field 0 to a 16-bit unsigned int and field 3 to a 32-bit float).

Massage the datatypes:

```

>>> adapter.set_field_types({0: 'u2', 3: 'f4'})
>>> array = adapter[:]
>>> array.dtype
dtype([('f1', '<u2'), ('f2', '<u8'), ('f3', '<f8'), ('f4', '<f4'),
      ('comment', 'O')])

```

The first five records:

```

>>> array = adapter[0:5]
>>> print(array)
[(0, 1222, 0.926116, 84.44437408447266, 'MlzvBRyquns')
 (1, 1350, 0.553585, 81.03726959228516, 'ikgEauJeTZvd')
 (2, 1932, 0.710919, 31.59865951538086, 'uUQmHJFZhniRecAvx')
 (3, 1494, 0.622391, 57.90607452392578, 'iWQBAZodkfHODtI')
 (4, 1981, 0.820246, 40.848018646240234, 'igxeXdBpqE')]

```

Read last five records:

```

>>> array = adapter[-5:]
>>> print(array)
[(5, 1267, 0.694631, 6.999039173126221, 'bRSrwitHeY')
 (6, 1166, 0.37465, 38.7022705078125, 'qzbMgVThXtHpFDNrd')
 (7, 1229, 0.390566, 55.338134765625, 'hyarmvWi')
 (8, 1816, 0.201106, 59.74718475341797, 'DcHymelRusO')
 (9, 1416, 0.725697, 42.50992965698242, 'QMUGRAwe')]

```

Read every other record:

```
>>> array = adapter[:,2]
>>> print(array)
[(0, 1222, 0.926116, 84.44437408447266, 'MlzvBRyquns'),
 (2, 1932, 0.710919, 31.59865951538086, 'uUQmHJFZhnirecAvx'),
 (4, 1981, 0.820246, 40.848018646240234, 'igxeXdBpqE'),
 (6, 1166, 0.37465, 38.7022705078125, 'qzbMgVThXtHpFDNrD'),
 (8, 1816, 0.201106, 59.74718475341797, 'DcHymelRusO')]
```

Read first and second, third fields only:

```
>>> array = adapter[[0,1,2]][:,]
>>> list(array)
[(0, 1222, 0.926116),
 (1, 1350, 0.553585),
 (2, 1932, 0.710919),
 (3, 1494, 0.622391),
 (4, 1981, 0.820246),
 (5, 1267, 0.694631),
 (6, 1166, 0.37465),
 (7, 1229, 0.390566),
 (8, 1816, 0.201106),
 (9, 1416, 0.725697)]
```

Read fields named 'f2' and 'comment' only:

```
>>> array = adapter[['f2', 'comment']][:]
>>> list(array)
[(1222, 'MlzvBRyquns'),
 (1350, 'ikgEauJeTZvd'),
 (1932, 'uUQmHJFZhnirecAvx'),
 (1494, 'iWQBAZodkfHODtI'),
 (1981, 'igxeXdBpqE'),
 (1267, 'bRSrwitHeY'),
 (1166, 'qzbMgVThXtHpFDNrD'),
 (1229, 'hyarmvWi'),
 (1816, 'DcHymelRusO'),
 (1416, 'QMUGRAwe')]
```

JSON Support

Text data in JSON format can be parsed by specifying 'json' for the parser argument:

Content of file data/one.json:

```
{"id":123, "name":"xxx"}
```

Single JSON object:

```
>>> adapter = iopro.text_adapter('data/one.json', parser='json')
>>> adapter[:]
array([(123, 'xxx')],
      dtype=[('id', '<u8'), ('name', 'O')])
```

Currently, each JSON object at the root level is interpreted as a single NumPy record. Each JSON object can be part of an array, or separated by a newline. Examples of valid JSON documents that can be parsed by IOPro, with the NumPy array result:

Content of file data/two.json:

```
[{"id":123, "name":"xxx"}, {"id":456, "name":"yyy"}]
```

Array of two JSON objects:

```
>>> iopro.text_adapter('data/two.json', parser='json')[:]
array([(123, 'xxx'), (456, 'yyy')],
      dtype=[('id', '<u8'), ('name', 'O')])
```

Content of file data/three.json:

```
{"id":123, "name":"xxx"}
{"id":456, "name":"yyy"}
```

Two JSON objects separated by newline:

```
>>> iopro.text_adapter('data/three.json', parser='json')[:]
array([(123, 'xxx'), (456, 'yyy')],
      dtype=[('id', '<u8'), ('name', 'O')])
```

Massaging data in the adapter

A custom function can be used to modify values as they are read.

```
>>> import iopro, io, math
>>> stream = io.StringIO('3,abc,3.3\n7,xxx,9.9\n4,,')
>>> adapter = iopro.text_adapter(stream, parser='csv', field_names=False)
```

Override default converter for first field:

```
>>> adapter.set_converter(0, lambda x: math.factorial(int(x)))
>>> adapter[:]
array([(6, 'abc', 3.3), (5040, 'xxx', 9.9), (24, '', nan)],
      dtype=[('f0', '<u8'), ('f1', 'O'), ('f2', '<f8')])
```

We can also force data types and set fill values for missing data.

Apply data types to columns:

```
>>> stream = io.StringIO('3,abc,3.3\n7,xxx,9.9\n4,,')
>>> adapter = iopro.text_adapter(stream, parser='csv', field_names=False)
>>> adapter.set_field_types({1:'S3', 2:'f4'})
>>> adapter[:]
array([(3, b'abc', 3.299999952316284), (7, b'xxx', 9.899999618530273),
      (4, b'', nan)],
      dtype=[('f0', '<u8'), ('f1', 'S3'), ('f2', '<f4')])
```

Set fill value for missing values in each field:

```
>>> adapter.set_fill_values({1:'ZZZ', 2:999.999})
>>> adapter[:]
array([(3, b'abc', 3.299999952316284), (7, b'xxx', 9.899999618530273),
      (4, b'ZZZ', 999.9990234375)],
      dtype=[('f0', '<u8'), ('f1', 'S3'), ('f2', '<f4')])
```

Combining regular expressions and typecasting

A later section discusses regular expressions in more detail. This example is a quick peek into using them with IOPro.

Content of the file `data/transactions.csv`:

```
$2.56, 50%, September 20 1978
$1.23, 23%, April 5 1981
```

Combining features:

```
>>> import iopro
>>> regex_string = '\$(\d)\.(\d{2}),\s*([0-9])\%,\s*([A-Za-z]+) '
>>> adapter = iopro.text_adapter('data/transactions.csv',
...                             parser='regex',
...                             regex_string=regex_string,
...                             field_names=False,
...                             infer_types=False)
```

Set dtype of fields and their names:

```
>>> adapter.set_field_types({0:'i2', 1:'u2', 2:'f4', 3:'S10'})
>>> adapter.set_field_names(['dollars', 'cents', 'percentage', 'month'])
>>> adapter[:]
array([(2, 56, 50.0, b'September'), (1, 23, 23.0, b'April')],
      dtype=[('dollars', '<i2'), ('cents', '<u2'),
             ('percentage', '<f4'), ('month', 'S10')])
```

Advanced TextAdapter

`iopro.loadtxt()` versus `iopro.genfromtxt()`

Within IOPro there are two closely related functions. `loadtxt()`, which we have been looking at, makes a more optimistic assumption that your data is well-formatted. `genfromtxt()` has a number of arguments for handling messier data, and special behaviors for dealing with missing data.

`loadtxt()` is already highly configurable for dealing with data under many CSV and other delimited formats. `genfromtxt()` contains a superset of these arguments.

Gzip Support

IOPro can decompress gzip'd data on the fly, simply by indicating a `compression` keyword argument.

```
>>> adapter = iopro.text_adapter('data.gz', parser='csv', compression='gzip')
>>> array = adapter[:]
```

As well as being able to store and work with your compressed data without having to decompress it first, you also do not need to sacrifice any performance in doing so. For example, with one test 419 MB CSV file of numerical data, and a 105 MB file of the same data compressed with gzip, the following are run times on a test machine for loading the entire contents of each file into a NumPy array. Exact performance will vary between machines, especially between machines with HDD and SSD architecture.:

```
- uncompressed: 13.38 sec
- gzip compressed: 14.54 sec
```

In the test, the compressed file takes slightly longer, but consider having to uncompress the file to disk before loading with IOPro:

- uncompressed: 13.38 sec
- gzip compressed: 14.54 sec
- gzip compressed (decompress to disk, then load): 21.56 sec

Indexing CSV Data

One of the most useful features of IOPro is the ability to index data to allow for fast random lookup.

For example, to retrieve the last record of the compressed 109 MB dataset we used above:

```
>>> adapter = iopro.text_adapter('data.gz', parser='csv', compression='gzip')
>>> array = adapter[-1]
```

Retrieving the last record into a NumPy array takes 14.82 sec. This is about the same as the time to read the entire array, because the entire dataset has to be parsed to get to the last record.

To make seeking faster, we can build an index:

```
>>> adapter.create_index('index_file')
```

The above method creates an index in memory and saves it to disk, taking 9.48 sec. Now when seeking to and reading the last record again, it takes a mere 0.02 sec.

Reloading the index only takes 0.18 sec. If you build an index once, you get near instant random access to your data forever (assuming the data remains static):

```
>>> adapter = iopro.text_adapter('data.gz', parser='csv',
...                               compression='gzip',
...                               index_name='index_file')
```

Let's try it with a moderate sized example. You can download this data from the [Exoplanets Data Explorer](#) site.

```
>>> adapter = iopro.text_adapter('data/exoplanets.csv.gz',
...                               parser='csv', compression='gzip')
>>> print(len(adapter[:]), "rows")
>>> print(', '.join(adapter.field_names[:3]),
...       '...%d more...\n' % (adapter.field_count-6),
...       ', '.join(adapter.field_names[-3:]))
2042 rows
name, mass, mass_error_min ...73 more...
    star_teff, star_detected_disc, star_magnetic_field
```

```
>>> adapter.field_types
{0: dtype('O'),
 1: dtype('float64'),
 2: dtype('float64'),
 3: dtype('O'),
 4: dtype('float64'),
 5: dtype('float64'),
 6: dtype('float64'),
 7: dtype('float64'),
 8: dtype('O'),
 9: dtype('float64'),
```

(continues on next page)

(continued from previous page)

```
[... more fields ...]
69: dtype('float64'),
70: dtype('float64'),
71: dtype('float64'),
72: dtype('float64'),
73: dtype('float64'),
74: dtype('O'),
75: dtype('float64'),
76: dtype('float64'),
77: dtype('O'),
78: dtype('uint64')}
```

Do some timing (using an IPython magic):

```
>>> %time row = adapter[-1]
CPU times: user 35 ms, sys: 471 µs, total: 35.5 ms
Wall time: 35.5 ms
```

```
>>> %time adapter.create_index('data/exoplanets.index')
CPU times: user 15.7 ms, sys: 3.35 ms, total: 19.1 ms
Wall time: 18.6 ms
```

```
>>> %time row = adapter[-1]
CPU times: user 18.3 ms, sys: 1.96 ms, total: 20.3 ms
Wall time: 20.1 ms
```

```
>>> new_adapter = iopro.text_adapter('data/exoplanets.csv.gz', parser='csv',
...                                 compression='gzip',
...                                 index_name='data/exoplanets.index')
```

```
>>> %time row = new_adapter[-1]
CPU times: user 17.3 ms, sys: 2.12 ms, total: 19.4 ms
Wall time: 19.4 ms
```

Regular Expressions

Some people, when confronted with a problem, think “I know, I’ll use regular expressions.” Now they have two problems. —Jamie Zawinski

IOPro supports using regular expressions to help parse messy data. Take for example the following snippet of actual NASDAQ stock data found on the Internet:

The content of the file `data/stocks.csv`:

```
Name,Symbol,Exchange,Range
Apple,AAPL,NasdaqNM,363.32 - 705.07
Google,GOOG,NasdaqNM,523.20 - 774.38
Microsoft,MSFT,NasdaqNM,24.30 - 32.95
```

The first three fields are easy enough: name, symbol, and exchange. The fourth field presents a bit of a problem. Let’s try IOPro’s regular expression based parser:

```
>>> regex_string = '([A-Za-z]+),([A-Z]{1,4}),([A-Za-z]+),'\
...               '(\d+\.\d{2})\s*\-\s*(\d+\.\d{2})'
>>> adapter = iopro.text_adapter('data/stocks.csv', parser='regex',
...                             regex_string=regex_string)
```

```
>>> # Notice that header does not now match the regex
>>> print(adapter.field_names)
['Name', 'Symbol', 'Exchange', 'Range', ' ', ' ', ' ', ' ']
```

```
>>> # We can massage the headers to reflect our match pattern
>>> info = adapter.field_names[0].split(',')[3]
>>> adapter.field_names = info + ["Low", "High"]
>>> adapter[:]
array([('Apple', 'AAPL', 'NasdaqNM', 363.32, 705.07),
      ('Google', 'GOOG', 'NasdaqNM', 523.2, 774.38),
      ('Microsoft', 'MSFT', 'NasdaqNM', 24.3, 32.95)],
      dtype=[('Name', 'O'), ('Symbol', 'O'),
            ('Exchange', 'O'), ('Low', '<f8'), ('High', '<f8')])
```

Regular expressions are compact and often difficult to read, but they are also very powerful. By using the above regular expression with the grouping operators ‘(’ and ‘)’, we can define exactly how each record should be parsed into fields. Let’s break it down into individual fields:

- ([A-Za-z]+) defines the first field (stock name) in our output array
- ([A-Z]{1-4}) defines the second (stock symbol)
- ([A-Za-z]+) defines the third (exchange name)
- (\d+\.\d{2}) defines the fourth field (low price)
- \s*\-\s* is skipped because it is not part of a group
- (\d+\.\d{2}) defines the fifth field (high price)

The output array contains five fields: three string fields and two float fields. Exactly what we want.

S3 Support

IOPro can parse CSV data stored in Amazon’s S3 cloud storage service. In order to access S3 files, you need to specify some credentials along with the resource you are accessing.

The first two parameters are your AWS access key and secret key, followed by the S3 bucket name and key name. The S3 CSV data is downloaded in 128K chunks and parsed directly from memory, bypassing the need to save the entire S3 data set to local disk.

Let’s take a look at what we have stored from the Health Insurance Marketplace data. There’s a little bit of code with BeautifulSoup just to prettify the raw XML query results.

```
>>> import urllib.request
>>> url = 'http://s3.amazonaws.com/product-training/'
>>> xml = urllib.request.urlopen(url).read()
```

```
>>> import bs4, re
>>> r = re.compile(r'^(\s*)', re.MULTILINE)
>>> def display(bs, encoding=None, formatter="minimal", indent=4):
...     print(r.sub(r'\1' * indent, bs.prettify(encoding, formatter)))
```

(continues on next page)

(continued from previous page)

```
>>> display(bs4.BeautifulSoup(xml, "xml"))
<?xml version="1.0" encoding="utf-8"?>
<ListBucketResult xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
  <Name>
    product-training
  </Name>
  <Prefix/>
  <Marker/>
  <MaxKeys>
    1000
  </MaxKeys>
  <IsTruncated>
    false
  </IsTruncated>
  <Contents>
    <Key>
      BusinessRules.csv
    </Key>
    <LastModified>
      2016-06-25T00:03:20.000Z
    </LastModified>
    <ETag>
      "a565ebede6a7e6e060cd4526a7ae4345"
    </ETag>
    <Size>
      8262590
    </Size>
    <StorageClass>
      STANDARD
    </StorageClass>
  </Contents>
  <Contents>
    [... more files ...]
  </Contents>
</ListBucketResult>
```

In simple form, we see details about some S3 resources. Let's access one of them. Note that you will need to fill in your actual AWS access key and secret key.

```
>>> user_name = "class1"
>>> aws_access_key = "ABCD"
>>> aws_secret_key = "EFGH/IJK"
>>> bucket = 'product-training'
>>> key_name = 'BusinessRules.csv' # 21k lines, 8MB
>>> # key_name = 'PlanAttributes.csv' # 77k lines, 95MB
>>> # key_name = 'Rate.csv.gz' # 13M lines, 2GB raw, 110MB compressed
>>> adapter = iopro.s3_text_adapter(aws_access_key, aws_secret_key,
...                                bucket, key_name)
>>> # Don't try with the really large datasets, works with the default one
>>> df = adapter.to_dataframe()
>>> df.iloc[:6,:6]
```

IOPro can also build an index for S3 data just as with disk based CSV data, and use the index for fast random access lookup. If an index file is created with IOPro and stored with the S3 dataset in the cloud, IOPro can use this remote index to download and parse just the subset of records requested. This allows you to generate an index file once and share it on the cloud along with the data set, and does not require others to download the entire index file to use it.

iopro.pyodbc First Steps

iopro.pyodbc extends pyodbc with methods that allow data to be fetched directly into numpy containers. These functions are faster than regular fetch calls in pyodbc, providing also the convenience of being returned in a container appropriate to fast analysis.

This notebook is intended to be a tutorial on iopro.pyodbc. Most of the material is applicable to pyodbc (and based on pyodbc tutorials). There will be some examples specific to iopro.pyodbc. When that's the case, it will be noted.

Concepts

In pyodbc there are two main classes to understand:

- connection
- cursor

A connection is, as its name says, a connection to a datasource. A datasource is your database. It may be a database handled by a DBMS or just a plain file. A cursor allows you to interface with statements. Interaction with queries and other commands is performed through a cursor. A cursor is associated to a connection and commands over a cursor are performed over that connection to the datasource. In order to use iopro.pyodbc you must import it:

```
>>> import iopro.pyodbc as pyodbc
```

Connection to a datasource

In order to operate with pyodbc you need to connect to a datasource. Typically this will be a database. This is done by creating a connection object. To create a connection object you need a connection string. This string describes the datasource to use as well as some extra parameters. You can learn more about connection strings here.:

```
>>> connection_string = '''DSN=SQLServerTest;DATABASE=Test'''
>>> connection = pyodbc.connect(connection_string)
```

pyodbc.connect supports a keyword parameter autocommit. This controls the way the connection is handle. The default value (False) means that the commands that modify the database statements need to be committed explicitly. All commands between commits will form a single transaction. If autocommit is enabled every command will be issued and committed. It is also possible to change autocommit status after the connection is established.:

```
>>> connection.autocommit = True #enable autocommit
>>> connection.autocommit = False # disable autocommit
```

When not in autocommit mode, you can end a transaction by either committing it or rolling it back.:

```
In[6]: connection.commit() # commit the transaction
In[7]: connection.rollback() # rollback the transaction
```

Note that commit/rollback is always performed at the connection level. pyodbc provides a commit/rollback method in the cursor objects, but they will act on the associated connection.

Working with cursors

Command execution in pyodbc is handled through cursors. You can create a cursor from a connection using the cursor() method. The first step is creating a cursor:

```
In[8]: cursor = connection.cursor()
```

With a cursor created, we can start issuing SQL commands using the execute method.

Creating a sample table

First, create a sample table in the database. The following code will create a sample table with three columns of different types.:

```
>>> def create_test_table(cursor):
...     try:
...         cursor.execute('drop table test_table')
...     except:
...         pass
...     cursor.execute('''create table test_table (
...                         name varchar(10),
...                         fval float(24),
...                         ival int)''')
...     cursor.commit()
>>> create_test_table(cursor)
```

Filling the sample table with sample data

After creating the table, rows can be inserted by executing insert into the table. Note you can pass parameters by placing a ? into the SQL statement. The parameters will be taken in order for the sequence appears in the next parameter.:

```
>>> cursor.execute('insert into test_table values (?, ?, ?)', ('foo', 3.0, 2))
>>> cursor.rowcount
1
```

Using executemany a sequence of parameters to the SQL statement can be passed and the statement will be executed many times, each time with a different parameter set. This allows us to easily insert several rows into the database so that we have a small test set:

```
>>> cursor.executemany('insert into test_table values (?, ?, ?)', [
...     ('several', 2.1, 3),
...     ('tuples', -1.0, 2),
...     ('can', 3.0, 1),
...     ('be', 12.0, -3),
...     ('inserted', 0.0, -2),
...     ('at', 33.0, 0),
...     ('once', 0.0, 0)
... ])
```

Remember that if autocommit is turned off the changes won't be visible to any other connection unless we commit.:

```
>>> cursor.commit() # remember this is a shortcut to connection.commit() method
```

Querying the sample data from the sample table

Having populated our sample database, we can retrieve the inserted data by executing select statements.:

```
>>> cursor.execute('''select * from test_table''')
<pyodbc.Cursor at 0x6803510>
```

After calling `execute` with the `select` statement we need to retrieve the data. This can be achieved by calling `fetch` methods in the cursor. `fetchone` fetches the next row in the cursor, returning it in a tuple:

```
>>> cursor.fetchone()
('foo', 3.0, 2)
```

`fetchmany` retrieves several rows at a time in a list of tuples:

```
>>> cursor.fetchmany(3)
[('several', 2.09999999046325684, 3), ('tuples', -1.0, 2), ('can', 3.0, 1)]
```

`fetchall` retrieves all the remaining rows in a list of tuples:

```
>>> cursor.fetchall()
[('be', 12.0, -3), ('inserted', 0.0, -2), ('at', 33.0, 0), ('once', 0.0, 0)]
```

All the calls to any kind of `fetch` advances the cursor, so the next `fetch` starts in the row after the last row fetched. `execute` returns the cursor object. This is handy to retrieve the full query by chaining `fetchall`. This results in a one-liner::

```
>>> cursor.execute('''select * from test_table''').fetchall()
[('foo', 3.0, 2),
 ('several', 2.09999999046325684, 3),
 ('tuples', -1.0, 2),
 ('can', 3.0, 1),
 ('be', 12.0, -3),
 ('inserted', 0.0, -2),
 ('at', 33.0, 0),
 ('once', 0.0, 0)]
```

iopro.pyodbc extensions

When using `iopro.pyodbc` it is possible to retrieve the results from queries directly into `numpy` containers. This is accomplished by using the new cursor methods `fetchdictarray` and `fetchsarray`.

fetchdictarray

`fetchdictarray` fetches the results of a query in a dictionary. By default `fetchdictarray` fetches all remaining rows in the cursor::

```
>>> cursor.execute('''select * from test_table''')
>>> dictarray = cursor.fetchdictarray()
>>> type(dictarray)
dict
```

The keys in the dictionary are the column names::

```
>>> dictarray.keys()
['ival', 'name', 'fval']
```

Each column name is mapped to a `numpy` array (`ndarray`) as its value::

```
>>> ', '.join([type(dictarray[i]).__name__ for i in dictarray.keys()])
'ndarray, ndarray, ndarray'
```

The types of the numpy arrays are inferred from the database column information. So for our columns we get an appropriate numpy type. Note that in the case of name the type is a string of 11 characters even if in test_table is defined as varchar(10). The extra parameter is there to null-terminate the string::

```
>>> ', '.join([repr(dictarray[i].dtype) for i in dictarray.keys()])
"dtype('int32'), dtype('|S11'), dtype('float32')"
```

The numpy arrays will have a shape containing a single dimension with the number of rows fetched::

```
>>> ', '.join([repr(dictarray[i].shape) for i in dictarray.keys()])
'(8L,), (8L,), (8L,)'
```

The values in the different column arrays are index coherent. So in order to get the values associated to a given row it suffices to access each column using the appropriate index. The following snippet shows this correspondence::

```
>>> print '\n'.join(
...     [' ', '.join(
...         [repr(dictarray[i][j]) for i in dictarray.keys()])
...         for j in range(dictarray['name'].shape[0])])
2, 'foo', 3.0
3, 'several', 2.0999999
2, 'tuples', -1.0
1, 'can', 3.0
-3, 'be', 12.0
-2, 'inserted', 0.0
0, 'at', 33.0
0, 'once', 0.0
```

Having the results in numpy containers makes it easy to use numpy to analyze the data::

```
>>> import numpy as np
>>> np.mean(dictarray['fval'])
6.5124998092651367
```

fetchdictarray accepts an optional parameter that places an upper bound to the number of rows to fetch. If there are not enough elements left to be fetched in the cursor the arrays resulting will be sized accordingly. This way it is possible to work with big tables in chunks of rows::

```
>>> cursor.execute('select * from test_table')
>>> dictarray = cursor.fetchdictarray(6)
>>> print dictarray['name'].shape
(6L,)
>>> dictarray = cursor.fetchdictarray(6)
>>> print dictarray['name'].shape
(2L,)
```

fetchsarray

fetchsarray fetches the result of a query in a numpy structured array::

```
>>> cursor.execute('select * from test_table')
>>> sarray = cursor.fetchsarray()
```

(continues on next page)

(continued from previous page)

```
>>> print sarray
[('foo', 3.0, 2) ('several', 2.09999999046325684, 3) ('tuples', -1.0, 2)
 ('can', 3.0, 1) ('be', 12.0, -3) ('inserted', 0.0, -2) ('at', 33.0, 0)
 ('once', 0.0, 0)]
```

The type of the result is a numpy array (ndarray)::

```
>>> type(sarray)
numpy.ndarray
```

The dtype of the numpy array contains the description of the columns and their types::

```
>>> sarray.dtype
dtype([('name', '<S11'), ('fval', '<f4'), ('ival', '<i4')])
```

The shape of the array will be one-dimensional, with cardinality equal to the number of rows fetched::

```
>>> sarray.shape
(8L,)
```

It is also possible to get the shape of a column. In this way it will look similar to the code needed when using dictarrays:

```
>>> sarray['name'].shape
(8L,)
```

In a structured array it is as easy to access data by row or by column::

```
>>> sarray['name']
array(['foo', 'several', 'tuples', 'can', 'be', 'inserted', 'at', 'once'],
      dtype='<S11')

>>> sarray[0]
('foo', 3.0, 2)
```

It is also very easy and efficient to feed data into numpy functions::

```
>>> np.mean(sarray['fval'])
6.5124998092651367
```

fetchdictarray vs fetchsarray

Both methods provide ways to input data from a database into a numpy-friendly container. The structured array version provides more flexibility extracting rows in an easier way. The main difference is in the memory layout of the resulting object. An in-depth analysis of this is beyond the scope of this notebook. Suffice it to say that you can view the dictarray laid out in memory as a structure of arrays (in fact, a dictionary or arrays), while the structured array would be laid out in memory like an array of structures. This can make a lot of difference performance-wise when working with large chunks of data.

iopro.pyodbc Enhanced Capabilities

Demo code showing the enhanced capabilities of iopro.pyodbc submodule

This demo shows the basic capabilities for the iopro.pyodbc module. It first will connect with the database of your choice by ODBC, create and fill a new table (market) and then retrieve data with different methods (fetchall(), fetchdictarray() and fetchsarray()).

Author: Francesc Altet, Anaconda

```
>>> import iopro.pyodbc as pyodbc
>>> # Open the database (use the most appropriate for you)
>>> connect_string = 'DSN=odbcsqlite;DATABASE=market.sqlite' # SQLite
>>> #connect_string = 'Driver={SQL Server};SERVER=MyWinBox;DATABASE=Test;USER=Devel;
↳PWD=XXX' # SQL Server
>>> #connect_string = 'DSN=myodbc3;UID=devel;PWD=XXX;DATABASE=test' # MySQL
>>> #connect_string = 'DSN=PSQL;UID=devel;PWD=XXX;DATABASE=test' # PostgreSQL
>>> connection = pyodbc.connect(connect_string)
>>> cursor = connection.cursor()
```

Create the test table (optional if already done)

```
>>> try:
...     cursor.execute('drop table market')
... except:
...     pass
>>> cursor.execute('create table market (symbol_ varchar(5), open_ float, low_ float,
↳high_ float, close_ float, volume_ int)')
```

Fill the test table (optional if already done)

```
>>> from time import time
>>> t0 = time()
>>> N = 1000*1000
>>> for i in xrange(N):
...     cursor.execute(
...         "insert into market(symbol_, open_, low_, high_, close_, volume_)"
...         " values (?, ?, ?, ?, ?, ?)",
...         (str(i), float(i), float(2*i), None, float(4*i), i))
>>> cursor.execute("commit") # not supported by SQLite
>>> t1 = time() - t0
>>> print "Stored %d rows in %.3fs" % (N, t1)
```

Do the query in the traditional way

```
>>> # Query of the full table using the traditional fetchall
>>> query = "select * from market"
>>> cursor.execute(query)
>>> %time all = cursor.fetchall()
CPU times: user 5.23 s, sys: 0.56 s, total: 5.79 s
Wall time: 7.09 s
```

Do the query and get a dictionary of NumPy arrays

```
>>> # Query of the full table using the fetchdictarray (retrieve a dictionary of
↳ arrays)
>>> cursor.execute(query)
>>> %time dictarray = cursor.fetchdictarray()
CPU times: user 0.92 s, sys: 0.10 s, total: 1.02 s
Wall time: 1.44 s
```

Peek into the retrieved data

```
>>> dictarray.keys()
['high_', 'close_', 'open_', 'low_', 'volume_', 'symbol_']
>>> dictarray['high_']
array([ nan,  nan,  nan, ...,  nan,  nan,  nan])
>>> dictarray['symbol_']
array(['0', '1', '2', ..., '99999', '99999', '99999'], dtype='<S6')
```

Do the query and get a NumPy structured array

```
>>> # Query of the full table using the fetchsarray (retrieve a structured array)
>>> cursor.execute(query)
>>> %time sarray = cursor.fetchsarray()
CPU times: user 1.08 s, sys: 0.11 s, total: 1.20 s
Wall time: 1.99 s
```

Peek into retrieved data

```
>>> sarray.dtype
dtype([('symbol_', 'S6'), ('open_', '<f8'), ('low_', '<f8'), ('high_', '<f8
↳ '), ('close_', '<f8'), ('volume_', '<i4')])
>>> sarray[0:10]
array([('0', 0.0, 0.0, nan, 0.0, 0), ('1', 1.0, 2.0, nan, 4.0, 1),
      ('2', 2.0, 4.0, nan, 8.0, 2), ('3', 3.0, 6.0, nan, 12.0, 3),
      ('4', 4.0, 8.0, nan, 16.0, 4), ('5', 5.0, 10.0, nan, 20.0, 5),
      ('6', 6.0, 12.0, nan, 24.0, 6), ('7', 7.0, 14.0, nan, 28.0, 7),
      ('8', 8.0, 16.0, nan, 32.0, 8), ('9', 9.0, 18.0, nan, 36.0, 9)],
      dtype=[('symbol_', 'S6'), ('open_', '<f8'), ('low_', '<f8'), ('high_', '&
↳ lt;f8'), ('close_', '<f8'), ('volume_', '<i4')])
>>> sarray['symbol_']
array(['0', '1', '2', ..., '99999', '99999', '99999'], dtype='<S6')
```

ioopro.pyodbc Cancelling Queries

Starting with version 1.5, the pyodbc submodule of IOPro makes it possible to cancel operations. This is done by exposing the SQLCancel ODBC function as a cancel method in the Cursor object.

A Simple Example

A very simple example would be:

```
conn = iopro.pyodbc.connect(conn_str)
cursor = conn.cursor()
cursor.execute('SELECT something FROM sample_table')
result = cursor.fetchone()
cursor.cancel()
```

This is not very interesting, and it doesn't add much to the functionality of pyodbc.

What makes the cancel method more interesting is that it is possible to cancel running statements that are blocking another thread.

A Sample With Threading

Having access to the cancel method it is possible to stop running queries following different criteria. For example, it would be possible to execute queries with a time-out. If the time runs out, the query gets cancelled.

```
import iopro.pyodbc
import time
import threading

def query_with_time_out(conn, query, timeout):
    def watchdog(cursor, time_out):
        time.sleep(wait_time)
        cursor.cancel()

    cursor = conn.cursor()

    t = threading.Thread(target=watchdog, args=(cursor, timeout))
    t.start()
    try:
        cursor.execute(query)

        result = cursor.fetchall()
    except iopro.pyodbc.Error:
        result = 'timed out'

    return result
```

This is just one possibility. As cursor exposes directly the SQLCancel, many opportunities open in implementing policies to cancel running queries.

Finishing notes

In order for this to work, the underlying ODBC driver must support SQLCancel.

The pyodbc submodule of IOPro releases the Python GIL when it calls ODBC, so while queries are being executed other Python threads continue to execute while the thread that performed the query is blocked. This allows for cancel to be called by another thread. Coupled with threading, the cancel method is a very useful primitive.

IOPro END USER LICENSE AGREEMENT

IOPro (“the Software Product”) and accompanying documentation is licensed and not sold. The Software Product is protected by copyright laws and treaties, as well as laws and treaties related to other forms of intellectual property. Continuum Analytics, Inc. (dba Anaconda, Inc.) or its subsidiaries, affiliates, and suppliers (collectively “Continuum”) own intellectual property rights in the Software Product. The Licensee’s (“you” or “your”) license to download, use, copy, or change the Software Product is subject to these rights and to all the terms and conditions of this End User License Agreement (“Agreement”).

Acceptance

YOU ACCEPT AND AGREE TO BE BOUND BY THE TERMS OF THIS AGREEMENT BY SELECTING THE “ACCEPT” OPTION AND DOWNLOADING THE SOFTWARE PRODUCT OR BY INSTALLING, USING, OR COPYING THE SOFTWARE PRODUCT. YOU MUST AGREE TO ALL OF THE TERMS OF THIS AGREEMENT BEFORE YOU WILL BE ALLOWED TO DOWNLOAD THE SOFTWARE PRODUCT. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, YOU MUST SELECT “DECLINE” AND YOU MUST NOT INSTALL, USE, OR COPY THE SOFTWARE PRODUCT.

Trial Period

You have the right to use IOPro on a single computer or group of computers for 30 days with no license. After 30 days you must purchase an appropriate license to use the software on one or more machines or stop using the software and remove it from all of your machines on which you installed the software.

License Grant

This Agreement entitles you to install and use one copy of the Software Product on as many machines as you will personally use. The Software Product is licensed to a particular user. Only the user to whom the software is licensed may use the software. You must obtain a license for as many users as you wish to use the software. In addition, you may make archival copies of the Software Product Installer.

Right to Updates

This license entitles you to updates to the Software Product for one year from the time of payment. The Software Product will continue to function and you may continue to use The Software Product and any updates you have received for as long as you would like however you will no longer be able to receive updates from Continuum unless this License is renewed. Please contact sales@anaconda.com with any questions or concerns.

Restrictions on Transfer

Without first obtaining the express written consent of Continuum, you may not assign your rights and obligations under this Agreement, or redistribute, encumber, sell, rent, lease, sublicense, or otherwise transfer your rights to the Software Product.

Restrictions on Use

You may not use, copy, or install the Software Product on any system where more than one user will be able to use the software unless you have purchased a license for each user of the system. You may not decompile, “reverse-engineer”,

disassemble, or otherwise attempt to derive the source code for the Software Product.

Restrictions on Alteration

You may not modify the Software Product or create any derivative work of the Software Product or its accompanying documentation. Derivative works include but are not limited to translations. You may not alter any files or libraries in any portion of the Software Product.

Restrictions on Copying

You may not copy any part of the Software Product except to the extent that licensed use inherently demands the creation of a temporary copy stored in computer memory and not permanently affixed on storage medium. You may make archival copies of the Software Product installer.

Limited Software Product Warranty

For a period of 60 days from the date of shipment or from the date that you download the Software Product, as applicable, Continuum warrants that when properly installed and used under normal conditions, the Software Product will perform substantially as advertised.

Disclaimer of Warranties and Limitation of Liability

UNLESS OTHERWISE EXPLICITLY AGREED TO IN WRITING BY CONTINUUM, CONTINUUM MAKES NO OTHER WARRANTIES, EXPRESS OR IMPLIED, IN FACT OR IN LAW, INCLUDING, BUT NOT LIMITED TO, ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE OTHER THAN AS SET FORTH IN THIS AGREEMENT OR IN THE LIMITED WARRANTY DOCUMENTS PROVIDED WITH THE SOFTWARE PRODUCT.

Continuum makes no warranty that the Software Product will meet your requirements or operate under your specific conditions of use. Continuum makes no warranty that operation of the Software Product will be secure, error free, or free from interruption. YOU MUST DETERMINE WHETHER THE SOFTWARE PRODUCT SUFFICIENTLY MEETS YOUR REQUIREMENTS FOR SECURITY AND UNINTERRUPTABILITY. YOU BEAR SOLE RESPONSIBILITY AND ALL LIABILITY FOR ANY LOSS INCURRED DUE TO FAILURE OF THE SOFTWARE PRODUCT TO MEET YOUR REQUIREMENTS. CONTINUUM WILL NOT, UNDER ANY CIRCUMSTANCES, BE RESPONSIBLE OR LIABLE FOR THE LOSS OF DATA ON ANY COMPUTER OR INFORMATION STORAGE DEVICE. UNDER NO CIRCUMSTANCES SHALL CONTINUUM, ITS DIRECTORS, OFFICERS, EMPLOYEES OR AGENTS BE LIABLE TO YOU OR ANY OTHER PARTY FOR INDIRECT, CONSEQUENTIAL, SPECIAL, INCIDENTAL, PUNITIVE, OR EXEMPLARY DAMAGES OF ANY KIND (INCLUDING LOST REVENUES OR PROFITS OR LOSS OF BUSINESS) RESULTING FROM THIS AGREEMENT, OR FROM THE FURNISHING, PERFORMANCE, INSTALLATION, OR USE OF THE SOFTWARE PRODUCT, WHETHER DUE TO A BREACH OF CONTRACT, BREACH OF WARRANTY, OR THE NEGLIGENCE OF CONTINUUM OR ANY OTHER PARTY, EVEN IF CONTINUUM IS ADVISED BEFOREHAND OF THE POSSIBILITY OF SUCH DAMAGES. TO THE EXTENT THAT THE APPLICABLE JURISDICTION LIMITS CONTINUUM'S ABILITY TO DISCLAIM ANY IMPLIED WARRANTIES, THIS DISCLAIMER SHALL BE EFFECTIVE TO THE MAXIMUM EXTENT PERMITTED.

Limitation of Remedies and Damages

Your remedy for a breach of this Agreement or of any warranty included in this Agreement is the correction or replacement of the Software Product. Selection of whether to correct or replace shall be solely at the discretion of

Continuum. Continuum reserves the right to substitute a functionally equivalent copy of the Software Product as a replacement. If Continuum is unable to provide a replacement or substitute Software Product or corrections to the Software Product, your sole alternate remedy shall be a refund of the purchase price for the Software Product exclusive of any costs for shipping and handling. Any claim must be made within the applicable warranty period. All warranties cover only defects arising under normal use and do not include malfunctions or failure resulting from misuse, abuse, neglect, alteration, problems with electrical power, acts of nature, unusual temperatures or humidity, improper installation, or damage determined by Continuum to have been caused by you. All limited warranties on the Software Product are granted only to you and are non-transferable. You agree to indemnify and hold Continuum harmless from all claims, judgments, liabilities, expenses, or costs arising from your breach of this Agreement and/or acts or omissions.

Governing Law, Jurisdiction and Costs

This Agreement is governed by the laws of Texas, without regard to Texas's conflict or choice of law provisions.

Export Regulations

Any use or distribution of IOPro is made under conditions that the user and/or distributor is in full compliance with all export and other governing laws of the United States of America, including full and ongoing compliance with the Export Administration Regulations (EAR) of the United States Department of Commerce. See www.commerce.gov/ and <http://www.bis.doc.gov/index.php/regulations/export-administration-regulations-ear>. Use or distribution of Continuum software products to any persons, entities or countries currently under US sanctions is strictly prohibited. IOPro is classified with an ECCN of 5D992 with no license required for export to non-embargoed countries.

The United States currently has embargoes against Cuba, Iran, North Korea, Sudan and Syria. The exportation, re-exportation, sale or supply, directly or indirectly, from the United States, or by a U.S. person wherever located, of any Continuum software to any of these countries is strictly prohibited without prior authorization by the United States Government. By accepting this Agreement, you represent to Continuum that you will comply with all applicable export regulations for IOPro.

Severability

If any provision of this Agreement shall be held to be invalid or unenforceable, the remainder of this Agreement shall remain in full force and effect. To the extent any express or implied restrictions are not permitted by applicable laws, these express or implied restrictions shall remain in force and effect to the maximum extent permitted by such applicable laws.

IOPro Release Notes

2016-07-30: 1.9.0

- Remove warnings and documentation for unsupported Numba use
- Rewrite most documentation for clarity and accuracy
- Improve unit tests

2016-04-05: 1.8.0:

- Add PostgresAdapter for reading data from PostgreSQL databases

- Add AccumuloAdapter for reading data from Accumulo databases

2015-10-09: 1.7.2:

- Fix an issue with pyodbc where result NumPy arrays could return uninitialized data after the actual data null character. Now it pads the results with nulls.

2015-05-04: 1.7.1

- Properly cache output string objects for better performance

2015-03-02: 1.7.0

- Add Python 3 support
- Add support for parsing utf8 text files
- Add ability to set/get field types in MongoAdapter

2015-02-02: 1.6.11

- Fix issue with escape char not being parsed correctly inside quoted strings

2014-12-17: 1.6.10

- Fix issue with using field filters with json parser

2014-12-02: 1.6.9

- Fix issue with json field names getting mixed up

2014-11-20: 1.6.8

- Fix issue with return nulls returning wrong “null” for large queries (more than 10000 rows) in some circumstances.
- Fix issue with reading slices of json data
- Change json parser so that strings fields of numbers do not get converted to number type by default
- Allow json field names to be specified with field_names constructor argument
- If user does not specify json field names, use json attribute names as field names in array result

2014-07-03: 1.6.7

- Fix issue when reading more than 10000 rows containing unicode strings in platform where ODBC uses UTF-16/UCS2 encoding (notably Windows and unixODBC). The resulting data could be corrupt.

2014-06-16: 1.6.6

- Fix possible segfault when dealing with unicode strings in platforms where ODBC uses UTF-16/UCS2 encoding (notably Windows and unixODBC)
- Add `iopro_set_text_limit` function to `iopro`. It globally limits the size of text fields read by `fetchdictarray` and `fetchsarray`. By default it is set to 1024 characters.
- Fix possible segfault in `fetchdictarray` and `fetchsarray` when failing to allocate some NumPy array. This could notably happen in the presence of “TEXT” fields. Now it will raise an `OutOfMemory` error.
- Add lazy loading of submodules in `IOPro`. This reduces upfront import time of `IOPro`. Features are imported as they are used for the first time.

2014-05-07: 1.6.5

- Fix crash when building textadapter index

2014-04-29: 1.6.4

- Fix default value for null strings in `IOPro/pyodbc` changed to be an empty string instead of ‘NA’. NA was not appropriate as it can collide with valid data (Namibia country code is ‘NA’, for example), and it failed with single character columns.
- Ignore `SQLRowCount` when performing queries with `fetchsarray` and `fetchdictarray`, since `SQLRowCount` sometimes returns incorrect number of rows.

2014-03-25: 1.6.3

- Fix SQL TINYINT is now returned as an unsigned 8 bit integer in `fetchdictarray`/`fetchsarray`. This is to match the range specified in SQL (0..255). It was being returned as a signed 8 bit integer before (range -128..127)
- Add Preliminary unicode string support in `fetchdictarray`/`fetchsarray`.

2014-02-12: 1.6.2

- Disable Numba support for version 0.12 due to lack of string support.

2014-01-30: 1.6.1

- Fix a regression that made possible some garbage in string fields when using `fetchdictarray`/`fetchsarray`.
- Fix a problem where heap corruption could happen in `IOPro.pyodbc` `fetchdictarray`/`fetchsarray` related to nullable string fields.
- Fix the allocation guard debugging code: `iopro.pyodbc.enable_mem_guards(True|False)` should no longer crash.
- Merge Vertica fix for cancelling queries

2013-10-30: 1.6.0

- Add JSON support
- Misc bug fixes
- Fix crash in IOPro.pyodbc when dealing with nullable datetimes in `fetch_dictarray` and `fetch_sarray`.

2013-06-12: 1.5.5

- Fix issue parsing negative ints with leading whitespace in csv data.

2013-06-10: 1.5.4

- Allow delimiter to be set to None for csv files with single field.
- Fill in missing csv fields with fill values.
- Fill in blank csv lines with fill values for pandas dataframe output.
- Allow list of field names for TextAdapter `field_names` parameter.
- Change default missing fill value to empty string for string fields.

2013-06-05: 1.5.3

- Temporary fix for IndexError exception in TextAdapter.`__read_slice` method.

2013-05-28: 1.5.2

- Add ability to specify escape character in csv data

2013-05-23: 1.5.1

- fixed coredump when using datetime with numpy < 1.7

2013-05-22: 1.5.0

- Added a cancel method to the Cursor object in `iopro.pyodbc`. This method wraps ODBC `SQLCancel`.
- DECIMAL and NUMERIC types are now working on `iopro.pyodbc` on regular fetch functions. They are still unsupported in `fetchsarray` and `fetchdict` and `fetchsarray`
- Add ftp support
- Performance improvements to S3 support
- Misc bug fixes

2013-04-05: 1.4.3

- Update loadtxt and genfromtxt to reflect numpy versions' behavior for dealing with whitespace (default to any whitespace as delimiter, and treat multiple whitespace as one delimiter)
- Add read/write field_names property
- Add support for pandas dataframes as output
- Misc bug fixes

Reference guide

TextAdapter

Contents

- *TextAdapter*
 - *Methods*
 - *Basic Usage*
 - *Advanced Usage*

The TextAdapter module reads CSV data and produces a NumPy array containing the parsed data. The following features are currently implemented:

- The TextAdapter engine is written in C to ensure text is parsed as fast as data can be read from the source. Text is read and parsed in small chunks instead of reading entire data into memory at once, which enables very large files to be read and parsed without running out of memory.
- Python slicing notation can be used to specify a subset of records to be read from the data source, as well as a subset of fields.
- Fields can be specified in any one of three ways: by a delimiter character, using fixed field widths, or by a regular expression. This enables a larger variety of CSV-like and other types of text files to be parsed.
- A gzipped file can be parsed without having to uncompress it first. Parsing speed is about the same as an uncompressed version of same file.
- An index of record offsets in a file can be built to allow fast random access to records. This index can be saved to disk and loaded again later.
- Converter functions can be specified for converting parsed text to proper dtype for storing in NumPy array.
- The TextAdapter engine has automatic type inference so the user does not have to specify dtypes of the output array. The user can still specify dtypes manually if desired.
- Remote data stored in Amazon S3 can be read. An index can be built and stored with S3 data. Index can be read remotely, allowing for random access to S3 data.

Methods

The TextAdapter module contains the following factory methods for creating TextAdapter objects:

text_adapter (source, parser='csv', compression=None, comment='#',

```
quote='\"', num_records=0, header=0, field_names=True, indexing=False, index_name=None,
encoding='utf-8')
```

Create a text adapter for reading CSV, JSON, or fixed width text files, or a text file defined by regular expressions.

source - filename, file object, StringIO object, BytesIO object, S3 key, http url, or python generator
 parser - Type of parser for parsing text. Valid parser types are 'csv', 'fixed width', 'regex', and 'json'.
 encoding - type of character encoding (current ascii and utf8 are supported)
 compression - type of data compression (currently only gzip is supported)
 comment - character used to indicate comment line
 quote - character used to quote fields
 num_records - limits parsing to specified number of records; defaults to all records
 header - number of lines in file header; these lines are skipped when parsing
 footer - number of lines in file footer; these lines are skipped when parsing
 indexing - create record index on the fly as characters are read
 index_name - name of file to write index to
 output - type of output object (numpy array or pandas dataframe)

If parser is set to 'csv', additional parameters include:

delimiter - Delimiter character used to define fields in data source. Default is ','.

If parser is set to 'fixed_width', additional parameters include:

field_widths - List of field widths

If parser is set to 'regex', additional parameters include:

regex - Regular expression used to define records and fields in data source. See the regular expression example in the Advanced Usage section.

s3_text_adapter (access_key, secret_key, bucket_name, key_name, remote_s3_index=False)

```
parser='csv', compression=None, comment='#', quote='\"', num_records=0, header=0,
field_names=True, indexing=False, index_name=None, encoding='utf-8')
```

Create a text adapter for reading a text file from S3. Text file can be CSV, JSON, fixed width, or defined by regular expressions

In addition to the arguments described for the text_adapter function above, the s3_text_adapter function also has the following parameters:

access_key - AWS access key
 secret_key - AWS secret key
 bucket_name - name of S3 bucket
 key_name - name of key in S3 bucket
 remote_s3_index - use remote S3 index (index name must be key name + '.idx' extension)

The TextAdapter object returned by the text_adapter factory method contains the following methods:

set_converter (field, converter)

Set converter function for field

field - field to apply converter function

converter - python function object

set_missing_values (missing_values)

Set strings for each field that represents a missing value

missing_values - dict of field name or number, and list of missing value strings

Default missing values: 'NA', 'NaN', 'inf', '-inf', 'None', 'none', ''

set_fill_values (fill_values, loose=False)

Set fill values for each field

fill_values - dict of field name or number, and fill value

loose - If value cannot be converted, and value does not match any of the missing values, replace with fill value anyway.

Default fill values for each data type: | int - 0 | float - numpy.nan | char - 0 | bool - False | object - numpy.nan | string - numpy.nan

create_index (index_name=None, density=1)

Create an index of record offsets in file

index_name - Name of file on disk used to store index. If None, index will be created in memory but not saved.

density - density of index. Value of 1 will index every record, value of 2 will index every other record, etc.

to_array ()

Parses entire data source and returns data as NumPy array object

to_dataframe ()

Parses entire data source and returns data as Pandas DataFrame object

The TextAdapter object contains the following properties:

size (readonly)

Number of records in data source. This value is only set if entire data source has been read or indexed, or number of records was specified in text_adapter factory method when creating object.

field_count (readonly)

Number of fields in each record

field_names

Field names to use when creating output NumPy array. Field names can be set here before reading data or in `text_adapter` function with `field_names` parameter.

field_types

NumPy dtypes for each field, specified as a dict of fields and associated dtype. (Example: `{0:'u4', 1:'f8', 2:'S10'}`)

field_filter

Fields in data source to parse, specified as a list of field numbers or names (Examples: `[0, 1, 2]` or `['f1', 'f3', 'f5']`). This filter stays in effect until it is reset to empty list, or is overridden with array slicing (Example: `adapter[[0, 1, 3, 4]][:]`).

See the NumPy data types documentation for more details: <http://docs.continuum.io/anaconda/numpy/reference/arrays.dtypes.html>

The TextAdapter object supports array slicing:

Read all records: `adapter[:]`

Read first 100 records: `adapter[0:100]`

Read last record (only if data has been indexed or entire dataset has been read once before): `adapter[-1]`

Read first field in all records by specifying field number: `adapter[0][:]`

Read first field in all records by specifying field name: `adapter['f0'][:]`

Read first and third fields in all records: `adapter[[0, 2]][:]`

Basic Usage

Create TextAdapter object for data source:

```
>>> import iopro
>>> adapter = iopro.text_adapter('data.csv', parser='csv')
```

Parse text and store records in NumPy array using slicing notation:

```
>>> # read all records
>>> array = adapter[:]

>>> # read first ten records
>>> array = adapter[0:10]

>>> # read last record
>>> array = adapter[-1]

>>> # read every other record
>>> array = adapter[::2]
```

Advanced Usage

user defined converter function for field 0:

```
>>> import iopro
>>> import io

>>> data = '1, abc, 3.3\n2, xxx, 9.9'
>>> adapter = iopro.text_adapter(io.StringIO(data), parser='csv', field_names=False)

>>> # Override default converter for first field
>>> adapter.set_converter(0, lambda x: int(x)*2)
>>> adapter[:]
array([(2L, ' abc', 3.3), (4L, ' xxx', 9.9)],
      dtype=[('f0', '<u8'), ('f1', 'S4'), ('f2', '<f8')])
```

overriding default missing and fill values:

```
>>> import iopro
>>> import io

>>> data = '1,abc,inf\n2,NA,9.9'
>>> adapter = iopro.text_adapter(io.StringIO(data), parser='csv', field_names=False)

>>> # Define field dtypes (example: set field 1 to string object and field 2 to float)
>>> adapter.field_types = {1:'O', 2:'f4'}

>>> # Define list of strings for each field that represent missing values
>>> adapter.set_missing_values({1:['NA'], 2:['inf']})

>>> # Set fill value for missing values in each field
>>> adapter.set_fill_values({1:'xxx', 2:999.999})
>>> adapter[:]
array([(' abc', 999.9990234375), ('xxx', 9.8999999618530273)],
      dtype=[('f0', 'O'), ('f1', '<f4')])
```

creating and saving tuple of index arrays for gzip file, and reloading indices:

```
>>> import iopro
>>> adapter = iopro.text_adapter('data.gz', parser='csv', compression='gzip')

>>> # Build index of records and save index to disk.
>>> adapter.create_index(index_name='index_file')

>>> # Create new adapter object and load index from disk.
>>> adapter = iopro.text_adapter('data.gz', parser='csv', compression='gzip',
↳ indexing=True, index_name='index_file')

>>> # Read last record
>>> adapter[-1]
array([(100, 101, 102)], dtype=[('f0', '<u4'), ('f1', '<u4'), ('f2', '<u4')])
```

Use regular expression for finer control of extracting data:

```
>>> import iopro
>>> import io
```

(continues on next page)

(continued from previous page)

```

>>> # Define regular expression to extract dollar amount, percentage, and month.
>>> # Each set of parentheses defines a field.
>>> data = '$2.56, 50%, September 20 1978\n$1.23, 23%, April 5 1981'
>>> regex_string = '([0-9]\.[0-9][0-9]+)\,\s ([0-9]+)\%\,\s ([A-Za-z]+)'
>>> adapter = iopro.text_adapter(io.StringIO(data), parser='regex', regex_
↳ string=regex_string, field_names=False, infer_types=False)

>>> # set dtype of field to float
>>> adapter.field_types = {0:'f4', 1:'u4', 2:'S10'}
>>> adapter[:]
array([(2.56, 50L, 'September'), (1.23, 23L, 'April')],
      dtype=[('f0', '<f8'), ('f1', '<u8'), ('f2', 'S9')])

```

iopro.pyodbc

This project is an enhancement of the Python database module for ODBC that implements the Python DB API 2.0 specification. You can see the original project here:

homepage <http://code.google.com/p/pyodbc>

source <http://github.com/mkleehammer/pyodbc>

source <http://code.google.com/p/pyodbc/source/list>

The enhancements are documented in this file. For general info about the pyodbc package, please refer to the original project documentation.

This module enhancement requires:

- Python 2.4 or greater
- ODBC 3.0 or greater
- NumPy 1.5 or greater (1.7 is required for datetime64 support)

The enhancements in this module consist mainly in the addition of some new methods for fetching the data after a query and put it in a variety of NumPy containers.

Using NumPy as data containers instead of the classical list of tuples has a couple of advantages:

- 1) The NumPy container is much more compact, and hence, it requires much less memory, than the original approach.
- 2) As a NumPy container can hold arbitrarily large arrays, it requires much less object creation than the original approach (one Python object per datum retrieved).

This means that this enhancements will allow to fetch data out of relational databases in a much faster way, while consuming significantly less resources.

API additions

Variables

- *pyodbc.npversion* The version for the NumPy additions

Methods

Cursor.fetchdictarray (size=cursor.arraysize)

This is similar to the original *Cursor.fetchmany(size)*, but the data is returned in a dictionary where the keys are the names of the columns and the values are NumPy containers.

For example, if a SELECT is returning 3 columns with names 'a', 'b' and 'c' and types *varchar(10)*, *integer* and *timestamp*, the returned object will be something similar to:

```
{ 'a': array([...], dtype='S11'),  
  'b': array([...], dtype=int32),  
  'c': array([...], dtype=datetime64[us]) }
```

Note that the *varchar(10)* type is translated automatically to a string type of 11 elements ('S11'). This is because the ODBC driver needs one additional space to put the trailing '0' in strings, and NumPy needs to provide the room for this.

Also, it is important to stress that all the *timestamp* types are translated into a NumPy *datetime64* type with a resolution of microseconds by default.

Cursor.fetchsarray (size=cursor.arraysize)

This is similar to the original *Cursor.fetchmany(size)*, but the data is returned in a NumPy structured array, where the name and type of the fields matches to those resulting from the SELECT.

Here it is an example of the output for the SELECT above:

```
array([(...),  
      (...)],  
      dtype=[('a', '<S11'), ('b', '<i4'), ('c', '<M8[us]', {})]])
```

Note that, due to efficiency considerations, this method is calling the *fetchdictarray()* behind the scenes, and then doing a conversion to get an structured array. So, in general, this is a bit slower than its *fetchdictarray()* counterpart.

Data types supported

The new methods listed above have support for a subset of the standard ODBC. In particular:

- String support (SQL_VARCHAR) is supported.
- Numerical types, be them integers or floats (single and double precision) are fully supported. Here it is the complete list: SQL_INTEGER, SQL_TINYINT, SQL_SMALLINT, SQL_FLOAT and SQL_DOUBLE.
- Dates, times, and timestamps are mapped to the *datetime64* and *timedelta* NumPy types. The list of supported data types are: SQL_DATE, SQL_TIME and SQL_TIMESTAMP,
- Binary data is not supported yet.
- Unicode strings are not supported yet.

NULL values

As there is not (yet) a definitive support for missing values (NA) in NumPy, this module represents NA data as particular values depending on the data type. Here it is the current table of the particular values:

```

int8: -128 (-2**7)
uint8: 255 (2**8-1)
int16: -32768 (-2**15)
uint16: 65535 (2**16-1)
int32: -2147483648 (-2**31)
uint32: 4294967295 (2**32-1)
int64: -9223372036854775808 (-2**63)
uint64: 18446744073709551615 (2**64-1)
float32: NaN
float64: NaN
datetime64: NaT
timedelta64: NaT (or -2**63)
string: 'NA'

```

Improvements for 1.1 release

- The rowcount is not trusted anymore for the *fetchdict()* and *fetchsarray()* methods. Now the NumPy containers are built incrementally, using realloc for a better use of resources.
- The Python interpreter does not exit anymore when fetching an exotic datatype not supported by NumPy.
- The docsstrings for *fetchdict()* and *fetchsarray()* have been improved.

MongoAdapter

Contents

- *MongoAdapter*
 - *Methods*
 - *Basic Usage*

The MongoAdapter module reads data from a Mongo database collection and produces a NumPy array containing the loaded. The following features are currently implemented:

- The MongoAdapter engine is written in C to ensure data is loaded fast with minimal memory usage.
- Python slicing notation can be used to specify the subset of records to be read from the data source.
- The MongoAdapter engine has automatic type inference so the user does not have to specify dtypes of the output array.

Methods

The MongoAdapter module contains the following constructor for creating MongoAdapter objects:

MongoAdapter (host, port, database, collection)

MongoAdapter constructor

host - Host name where Mongo database is running.

port - Port number where Mongo database is running.

database - Mongo database to connect to

collection - Mongo database collection

set_field_names (names)

Set field names to read when creating output NumPy array.

get_field_names ()

Returns names of fields that will be read when reading data from Mongo database.

set_field_types (types=None)

Set NumPy dtypes for each field, specified as a dict of field names/indices and associated dtype. (Example: {0:'u4', 1:'f8', 2:'S10'})

get_field_types ()

Returns dict of field names/indices and associated NumPy dtype.

The MongoAdapter object contains the following properties:

size (readonly)

Number of documents in the Mongo database + collection specified in constructor.

Basic Usage

1. Create MongoAdapter object for data source

```
>>> import iopro
>>> adapter = iopro.MongoAdapter('localhost', 27017, 'database_name', 'collection_
↳name')
```

2. Load Mongo collection documents into NumPy array using slicing notation

```
>>> # read all records for 'field0' field
>>> array = adapter['field0'][:]
```

```
>>> # read first ten records for 'field0' and 'field1' fields
>>> array = adapter[['field0', 'field1']][0:10]
```

```
>>> # read last record
>>> array = adapter['field0'][-1]
```

```
>>> # read every other record
>>> array = adapter['field0'][:,2]
```

Accumulo Adapter

Contents

- *Accumulo Adapter*

- *Adapter Methods*
- *Adapter Properties*
- *Basic Usage*

The AccumuloAdapter module reads data from Accumulo key/value stores and produces a NumPy array containing the parsed values.

- The AccumuloAdapter engine is written in C to ensure returned data is parsed as fast as data can be read from the source. Data is read and parsed in small chunks instead of reading entire data into memory at once.
- Python slicing notation can be used to specify a subset of records to be read from the data source.

Adapter Methods

Accumulo Adapter Constructor:

AccumuloAdapter (server='localhost', port=42424, username='', password='', table=None, field_type='f8', start_key=None, stop_key=None, start_key_inclusive=True, stop_key_inclusive=False, missing_values=None, fill_value=None):

Create an adaptor for connecting to an Accumulo key/value store.

server: Accumulo server address

port: Accumulo port

username: Accumulo user name

password: Accumulo user password

table: Accumulo table to read data from

field_type: str, NumPy dtype to interpret table values as

start_key: str, key of record where scanning will start from

stop_key: str, key of record where scanning will stop at

start_key_inclusive: If True, start_key is inclusive (default is True)

stop_key_inclusive: If True, stop_key is inclusive (default is False)

missing_values: list, missing value strings. Any values in table equal to one of these strings will be replaced with fill_value.

fill_value: fill value used to replace missing value when scanning

close ()

Close connection to the database.

The AccumuloAdapter object supports array slicing:

Read all records: adapter[:]

Read first ten records: adapter[0:10]

Read last record: adapter[-1]

Read every other record: adapter[::2]

Adapter Properties

field_type (readonly)

Get dtype of output NumPy array

start_key

Get/set key of record where reading/scanning will start.

The start_key_inclusive property specifies whether this key is inclusive (default is inclusive).

stop_key

Get/set key of record where reading/scanning will stop.

The stop_key_inclusive property specifies whether this key is inclusive (default is exclusive).

start_key_inclusive

Toggle whether start key is inclusive. Default is true.

stop_key_inclusive

Toggle whether stop key is inclusive. Default is False.

missing_values

Get/Set missing value strings. Any values in Accumulo table matching one of these strings will be replaced with fill_value.

fill_value

Fill value used to replace missing_values. Fill value type should match specified output type.

Basic Usage

Create AccumuloAdapter object for data source:

```
>>> import iopro
>>> adapter = iopro.AccumuloAdapter(server='172.17.0.1',
                                   port=42424,
                                   username='root',
                                   password='password',
                                   field_type='f4',
                                   table='iopro_tutorial_data')
```

IOPro adapters use slicing to retrieve data. To retrieve records from the table or query, the standard NumPy slicing notation can be used:

```
>>> # read all records
>>> array = adapter[:]
array([ 0.5,  1.5,  2.5,  3.5,  4.5], dtype=float32)
```

```
>>> # read first three records
>>> array = adapter[0:3]
array([ 0.5,  1.5,  2.5], dtype=float32)
```

```
>>> # read every other record from the first four records
>>> array = adapter[:4:2]
array([ 0.5,  2.5], dtype=float32)
```

The Accumulo adapter does not support seeking from the last record.

The `field_types` property can be used to see what type the output NumPy array will have:

```
>>> adapter.field_type
'f4'
```

Since Accumulo is essentially a key/value store, results can be filtered based on key. For example, a start key using the `start_key` property. This will retrieve all values with a key equal to or greater than the start key.

```
>>> adapter.start_key = 'row02'
>>> adapter[:]
array([ 1.5,  2.5,  3.5,  4.5], dtype=float32)
```

Likewise, a stop key. This will retrieve all values with a key less than the stop key but equal to or greater than the start key.

```
>>> adapter.stop_key = 'row04'
>>> adapter[:]
array([ 1.5,  2.5], dtype=float32)
```

By default, the start key is inclusive. This can be changed by setting the `start_key_inclusive` property to `False`.

```
>>> adapter.start_key_inclusive = False
>>> adapter[:]
array([ 2.5], dtype=float32)
```

By default, the stop key is exclusive. This can be changed by setting the `stop_key_inclusive` property to `True`.

```
>>> adapter.stop_key_inclusive = True
>>> adapter[:]
array([ 2.5,  3.5], dtype=float32)
```

The Accumulo adapter can handle missing values. If it is known that the strings 'NA' and 'nan' signify missing float values, the `missing_values` property can be used to tell the adapter to treat these strings as missing values: Also, the `fill_value` property can be used to specify what value to replace missing values with.

```
>>> adapter = iopro.AccumuloAdapter('172.17.0.1', 42424, 'root', 'password', 'iopro_
↳tutorial_missing_data', field_type='S10')
>>> adapter[:]
array([b'NA', b'nan'], dtype='<S10')
```

```
>>> adapter = iopro.AccumuloAdapter('172.17.0.1', 42424, 'root', 'secret', 'iopro_
↳tutorial_missing_data', field_type='f8')
>>> adapter.missing_values = ['NA', 'nan']
>>> adapter.fill_value = np.nan
>>> adapter[:]
array([ nan,  nan])
```

Close database connection:

```
>>> adapter.close()
```

PostgresAdapter, PostGIS, and GreenPlum

Contents

- *PostgresAdapter, PostGIS, and GreenPlum*
 - *Adapter Methods*
 - *Adapter Properties*
 - *Basic Usage*

The PostgresAdapter module reads data from PostgreSQL based databases and produces a NumPy array or a Pandas Dataframe containing the parsed data. The PostgresAdapter can be used to access data from PostgreSQL and GreenPlum, and has enhancements to support PostGIS points, lines, multilines, polygons, and multipolygons. The following features are currently implemented:

- The PostgresAdapter engine is written in C to ensure returned data is parsed as fast as data can be read from the source. Data is read and parsed in small chunks instead of reading entire data into memory at once.
- Python slicing notation can be used to specify a subset of records to be read from the data source.
- A subset of columns can be specified to be returned instead of returning all columns for the records.

Adapter Methods

PostgreSQL Adapter Constructor:

PostgresAdapter (connection_uri, table=None, query=None, field_filter=None, dataframe=False, field_names=None, field_types=None, field_shapes=None):

Create an adaptor for connecting to a PostgreSQL based database.

connection_uri: string URI describing how to connect to database

table: string, name of table to read records from. Only table parameter or query parameter can be set, but not both.

query: string, custom query to use for reading records. Only query parameter or table parameter can be set, but not both. field_filter parameter cannot be set when query parameter is set (since it is trivial to specify fields in query string).

field_filter: names of fields include in query (only valid when table parameter is specified)

dataframe: bool, return results as dataframe instead of array

field_names: list, names of fields in output array or dataframe. Defaults to database table column names.

field_types: list, NumPy dtype for each field in output array or dataframe. Defaults to database table column types.

field_shapes: list, shape of each field value for geometry field types with variable length data. For example, for a 'path' database column with 2d points, the points of the path will be stored in a list object by default. If a field shape of '10' is specified, the points will be stored in a 2x10 float subarray (2 floats per point* 10 points max). A field shape of the form (x,y) should be specified for types like multipolygon where x is the max number of polygons and y is the max length of each polygon (the size of the point is inferred).

close ()

Close connection to the database.

The PostgresAdapter object supports array slicing:

Read all records: `adapter[:]`

Read first 100 records: `adapter[0:100]`

Read last record: `adapter[-1]`

Read every other record: `adapter[::2]`

Adapter Properties

num_records (readonly)

Get number of records that will be returned from table or custom query.

num_fields (readonly)

Get number of fields in records that will be returned from table or custom query

field_names

Get/set names of fields in final array or dataframe. Field names can be set by specifying a list of names, or dict mapping of field number to field name. If names is a list, the length of list must match the number of fields in data set. If names is a dict, the field name from the database will be used if no name in dict is specified for that field.

field_types

Get/set field types in final array or dataframe. Field types can be set by specifying a list of NumPy dtypes, or a dict mapping of field number or name to field type. If types is a list, the length of list must match the number of fields in data set. If types is a dict, the field type from the database will be used if type is not specified in dict.

field_shapes

Get/set field shapes for variable length fields. Field shapes can be set by specifying a list of shape tuples (or a single integer if shape has one dimension), or a dict mapping of field number or name to field shape. If shapes is a list, the length of the list must match the number of fields in data set. A value of None or zero for a field, or an unspecified shape, means that an infinite length value will be allowed for field, and value will be stored in Python list object if field is PostgreSQL geometry type, or as Well Known Text string objects if field is PostGIS type.

Basic Usage

Create PostgresAdapter object for data source:

```
>>> import iopro
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=db_name user=user_
↳table=table_name')
```

IOPro adapters use slicing to retrieve data. To retrieve records from the table or query, the standard NumPy slicing notation can be used:

```
>>> # read all records
>>> array = adapter[:]
```

```
>>> # read first ten records
>>> array = adapter[0:10]
```

```
>>> # read last record
>>> array = adapter[-1]
```

```
>>> # read every other record
>>> array = adapter[::2]
```

The PostgreSQL adapter has a few properties that we can use to find out more about our data. To get the number of records in our dataset:

```
>>> adapter.num_records
5
```

or the number of fields:

```
>>> adapter.num_fields
5
```

To find the names of each field:

```
>>> adapter.field_names
['field1', 'real', 'name', 'point2d', 'multipoint3d']
```

These names come from the names of the columns in the database and are used by default for the field names in the NumPy array result. These names can be changed by setting the field names property using a list of field names:

```
>>> adapter.field_names = ['field1', 'field2', 'field3', 'field4', 'field5']
>>> adapter[:].dtype
dtype([('field1', '<i4'), ('field2', '<f4'), ('field3', '<U10'), ('field4', '<f8', (2,
↪)), ('field5', 'O'))]
```

Individual fields can also be set by using a dict, where the key is the field number and the value is the field name we want:

```
>>> adapter.field_names = {1: 'AAA'}
>>> adapter[:].dtype
dtype([('integer', '<i4'), ('AAA', '<f4'), ('string', '<U10'), ('point2d', '<f8', (2,
↪)), ('multipoint3d', 'O')])
```

To find out the NumPy dtype of each field:

```
>>> adapter.field_types
['i4', 'f4', 'U10', 'f8', 'O']
```

Similar to the field names property, the types property can be set using a list or dict to force a field to be cast to a specific type:

```
>>> adapter.field_types = {0: 'f4', 1: 'i4', 2: 'U3', 4: 'O'}
```

To filter the fields returned by passing a list of field names to the constructor:

```
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=db_name user=user',
                                     table='data',
                                     field_filter=['field1', 'field2'])
```

For fields like path or multipoint3d with a variable length, the adapter will return values as a list of tuples containing the float components of each point (if a PostgreSQL geometric type) or as string objects in Well Known Text format (if a PostGIS type). For improved performance, a field shape can be specified which will set the max dimensions of the field values. For example, a multipoint3d field can be set to have a maximum of two points so that each set of 3d points will be stored in a 2x3 subarray of floats:

```
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=db_name user=user'
                                     table='data',
                                     field_filter=['multipoint3d'],
                                     field_shapes={'multipoint3d': 2})

>>> adapter[:]
array([([[0.0, 1.0, 2.0], [3.0, 4.0, 5.0]]),
       ([[6.0, 7.0, 8.0], [9.0, 10.0, 11.0]]),
       ([[12.0, 13.0, 14.0], [15.0, 16.0, 17.0]]),
       ([[18.0, 19.0, 20.0], [21.0, 22.0, 23.0]]),
       ([[24.0, 25.0, 26.0], [27.0, 28.0, 29.0]])],
      dtype=[('multipoint3d', '<f8', (2, 3))])
```

For more advanced queries, a custom select query can be passed to the constructor. Either a table name or a custom query can be passed to the constructor, but not both.

```
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=db_name user=user',
                                     query='select integer, string from data where_
↳ data.integer > 2')
>>> adapter[:]
```

Data can also be returned as a pandas dataframe using the adapter constructor's dataframe' argument:

```
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=iopro_tutorial user=jayvius
↳ ',
                                     table='data',
                                     dataframe=True)
```

To retrieve some PostGIS data that falls within a given bounding box:

```
>>> adapter = iopro.PostgresAdapter('host=localhost dbname=db_name user=user',
                                     query='select integer, point2d from data '
↳ 'where data.point2d @ ST_MakeEnvelope(0, 0,
↳ 4, 4) ')
```

Close database connection:

```
>>> adapter.close()
```

iopro.loadtxt

Load data from a text file.

Each row in the text file must have the same number of values.

Parameters

fname [file or str] File, filename, or generator to read. If the filename extension is `.gz` or `.bz2`, the file is first decompressed. Note that generators should return byte strings for Python 3k.

dtype [data-type, optional] Data-type of the resulting array; default: `float`. If this is a record data-type, the resulting array will be 1-dimensional, and each row will be interpreted as an element of the array. In this case, the number of columns used must match the number of fields in the data-type.

comments [str, optional] The character used to indicate the start of a comment; default: `'#'`.

delimiter [str, optional] The string used to separate values. By default, this is any whitespace.

converters [dict, optional] A dictionary mapping column number to a function that will convert that column to a float. E.g., if column 0 is a date string: `converters = {0: datestr2num}`. Converters can also be used to provide a default value for missing data (but see also `iopro.genfromtxt`): `converters = {3: lambda s: float(s.strip() or 0)}`. Default: `None`.

skiprows [int, optional] Skip the first *skiprows* lines; default: 0.

usecols [sequence, optional] Which columns to read, with 0 being the first. For example, `usecols = (1, 4, 5)` will extract the 2nd, 5th and 6th columns. The default, `None`, results in all columns being read.

unpack [bool, optional] If `True`, the returned array is transposed, so that arguments may be unpacked using `x, y, z = iopro.loadtxt(...)`. When used with a record data-type, arrays are returned for each field. Default is `False`.

ndmin [int, optional] The returned array will have at least *ndmin* dimensions. Otherwise mono-dimensional axes will be squeezed. Legal values: 0 (default), 1 or 2. .. versionadded:: 1.6.0

Returns

out [ndarray] Data read from the text file.

See Also

`iopro.genfromtxt` : Load data with missing values handled as specified.

Examples

simple parse of StringIO object data

```
>>> import iopro
>>> from io import StringIO # StringIO behaves like a file object
>>> c = StringIO("0 1\n2 3")
>>> iopro.loadtxt(c)
>>> array([[ 0.,  1.],
          [ 2.,  3.]])
```

set dtype of output array

```
>>> d = StringIO("M 21 72\nF 35 58")
>>> iopro.loadtxt(d, dtype={'names': ('gender', 'age', 'weight'),
...                          'formats': ('S1', 'i4', 'f4')})
>>> array([('M', 21, 72.0), ('F', 35, 58.0)],
          dtype=[('gender', '<|S1'), ('age', '<i4'), ('weight', '<f4')])
```

set delimiter and columns to parse

```

>>> c = StringIO("1,0,2\\n3,0,4")
>>> x, y = iopro.loadtxt(c, delimiter=',', usecols=(0, 2), unpack=True)
>>> x
array([ 1.,  3.])
>>> y
array([ 2.,  4.])

```

iopro.genfromtxt

Load data from a text file, with missing values handled as specified.

Each line past the first *skip_header* lines is split at the *delimiter* character, and characters following the *comments* character are discarded.

Parameters

fname [file or str] File, filename, or generator to read. If the filename extension is *.gz* or *.bz2*, the file is first decompressed. Note that generators must return byte strings in Python 3k.

dtype [dtype, optional] Data type of the resulting array. If *None*, the dtypes will be determined by the contents of each column, individually.

comments [str, optional] The character used to indicate the start of a comment. All the characters occurring on a line after a comment are discarded

delimiter [str, int, or sequence, optional] The string used to separate values. By default, any consecutive whitespaces act as delimiter. An integer or sequence of integers can also be provided as width(s) of each field.

skip_header [int, optional] The numbers of lines to skip at the beginning of the file.

skip_footer [int, optional] The numbers of lines to skip at the end of the file

converters [variable, optional] The set of functions that convert the data of a column to a value. The converters can also be used to provide a default value for missing data: `converters = {3: lambda s: float(s or 0)}`.

missing_values [variable, optional] The set of strings corresponding to missing data.

filling_values [variable, optional] The set of values to be used as default when the data are missing.

usecols [sequence, optional] Which columns to read, with 0 being the first. For example, `usecols = (1, 4, 5)` will extract the 2nd, 5th and 6th columns.

names [{None, True, str, sequence}, optional] If *names* is *True*, the field names are read from the first valid line after the first *skip_header* lines. If *names* is a sequence or a single-string of comma-separated names, the names will be used to define the field names in a structured dtype. If *names* is *None*, the names of the dtype fields will be used, if any.

excludelist [sequence, optional] A list of names to exclude. This list is appended to the default list ['return', 'file', 'print']. Excluded names are appended an underscore: for example, *file* would become *file_*.

deletechars [str, optional] A string combining invalid characters that must be deleted from the names.

defaultfmt [str, optional] A format used to define default field names, such as “f%i” or “f_%02i”.

autostrip [bool, optional] Whether to automatically strip white spaces from the variables.

replace_space [char, optional] Character(s) used in replacement of white spaces in the variables names. By default, use a `'_'`.

case_sensitive [{True, False, 'upper', 'lower'}, optional] If True, field names are case sensitive. If False or 'upper', field names are converted to upper case. If 'lower', field names are converted to lower case.

unpack [bool, optional] If True, the returned array is transposed, so that arguments may be unpacked using `x, y, z = loadtxt(...)`

usemask [bool, optional] If True, return a masked array. If False, return a regular array.

invalid_raise [bool, optional] If True, an exception is raised if an inconsistency is detected in the number of columns. If False, a warning is emitted and the offending lines are skipped.

Returns

out [ndarray] Data read from the text file. If *usemask* is True, this is a masked array.

See Also

`iopro.loadtxt` : equivalent function when no data is missing.

Notes

- When spaces are used as delimiters, or when no delimiter has been given as input, there should not be any missing data between two fields.
- When the variables are named (either by a flexible dtype or with *names*, there must not be any header in the file (else a `ValueError` exception is raised).
- Individual values are not stripped of spaces by default. When using a custom converter, make sure the function does remove spaces.

Examples

```
>>> import iopro
>>> from io import StringIO
```

Comma delimited file with mixed dtype

```
>>> s = StringIO("1,1.3,abcde")
>>> data = iopro.genfromtxt(s, dtype=[('myint', 'i8'), ('myfloat', 'f8'),
... ('mystring', 'S5')], delimiter=",")
>>> data
array((1, 1.3, 'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', '|S5')])
```

Using `dtype = None`

```
>>> s.seek(0) # needed for StringIO example only
>>> data = iopro.genfromtxt(s, dtype=None,
... names = ['myint', 'myfloat', 'mystring'], delimiter=",")
>>> data
```

(continues on next page)

(continued from previous page)

```
array((1, 1.3, 'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', '|S5')])
```

Specifying dtype and names

```
>>> s.seek(0)
>>> data = iopro.genfromtxt(s, dtype="i8,f8,S5",
... names=['myint', 'myfloat', 'mystring'], delimiter=",")
>>> data
array((1, 1.3, 'abcde'),
      dtype=[('myint', '<i8'), ('myfloat', '<f8'), ('mystring', '|S5')])
```

An example with fixed-width columns

```
>>> s = StringIO("11.3abcde")
>>> data = iopro.genfromtxt(s, dtype=None, names=['intvar', 'fltvar', 'strvar'],
... delimiter=[1,3,5])
>>> data
array((1, 1.3, 'abcde'),
      dtype=[('intvar', '<i8'), ('fltvar', '<f8'), ('strvar', '|S5')])
```
